Overview of Terminology Aspects

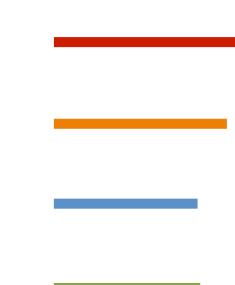

Genome (DNA or RNA)

Monopartite

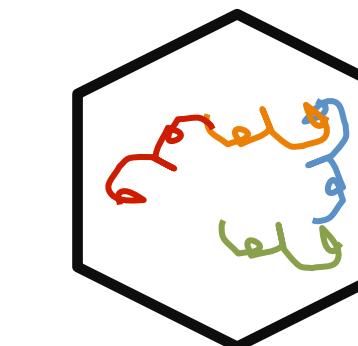

Multipartite

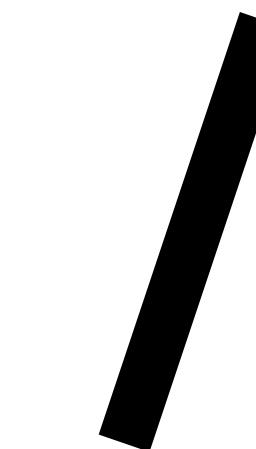

Segmented

Virion

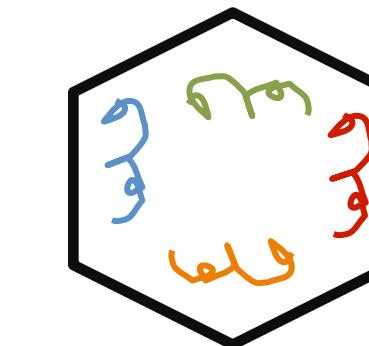

or

e.g. Adenovirus

e.g. Tobacco mosaic virus

e.g. Influenza A virus (8 segments)

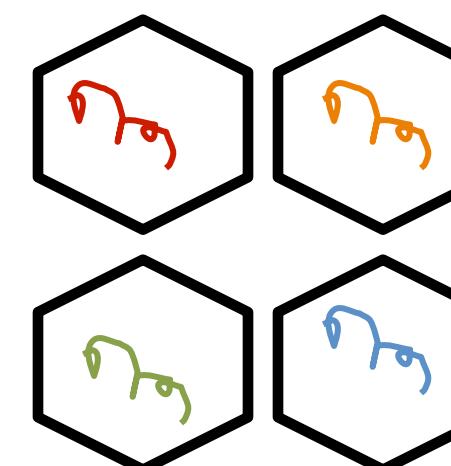

Designation

Monopartite

Segmented

Multipartite

One/many kinds (=> increased virion stability; Ojosnegros et al. 2011)

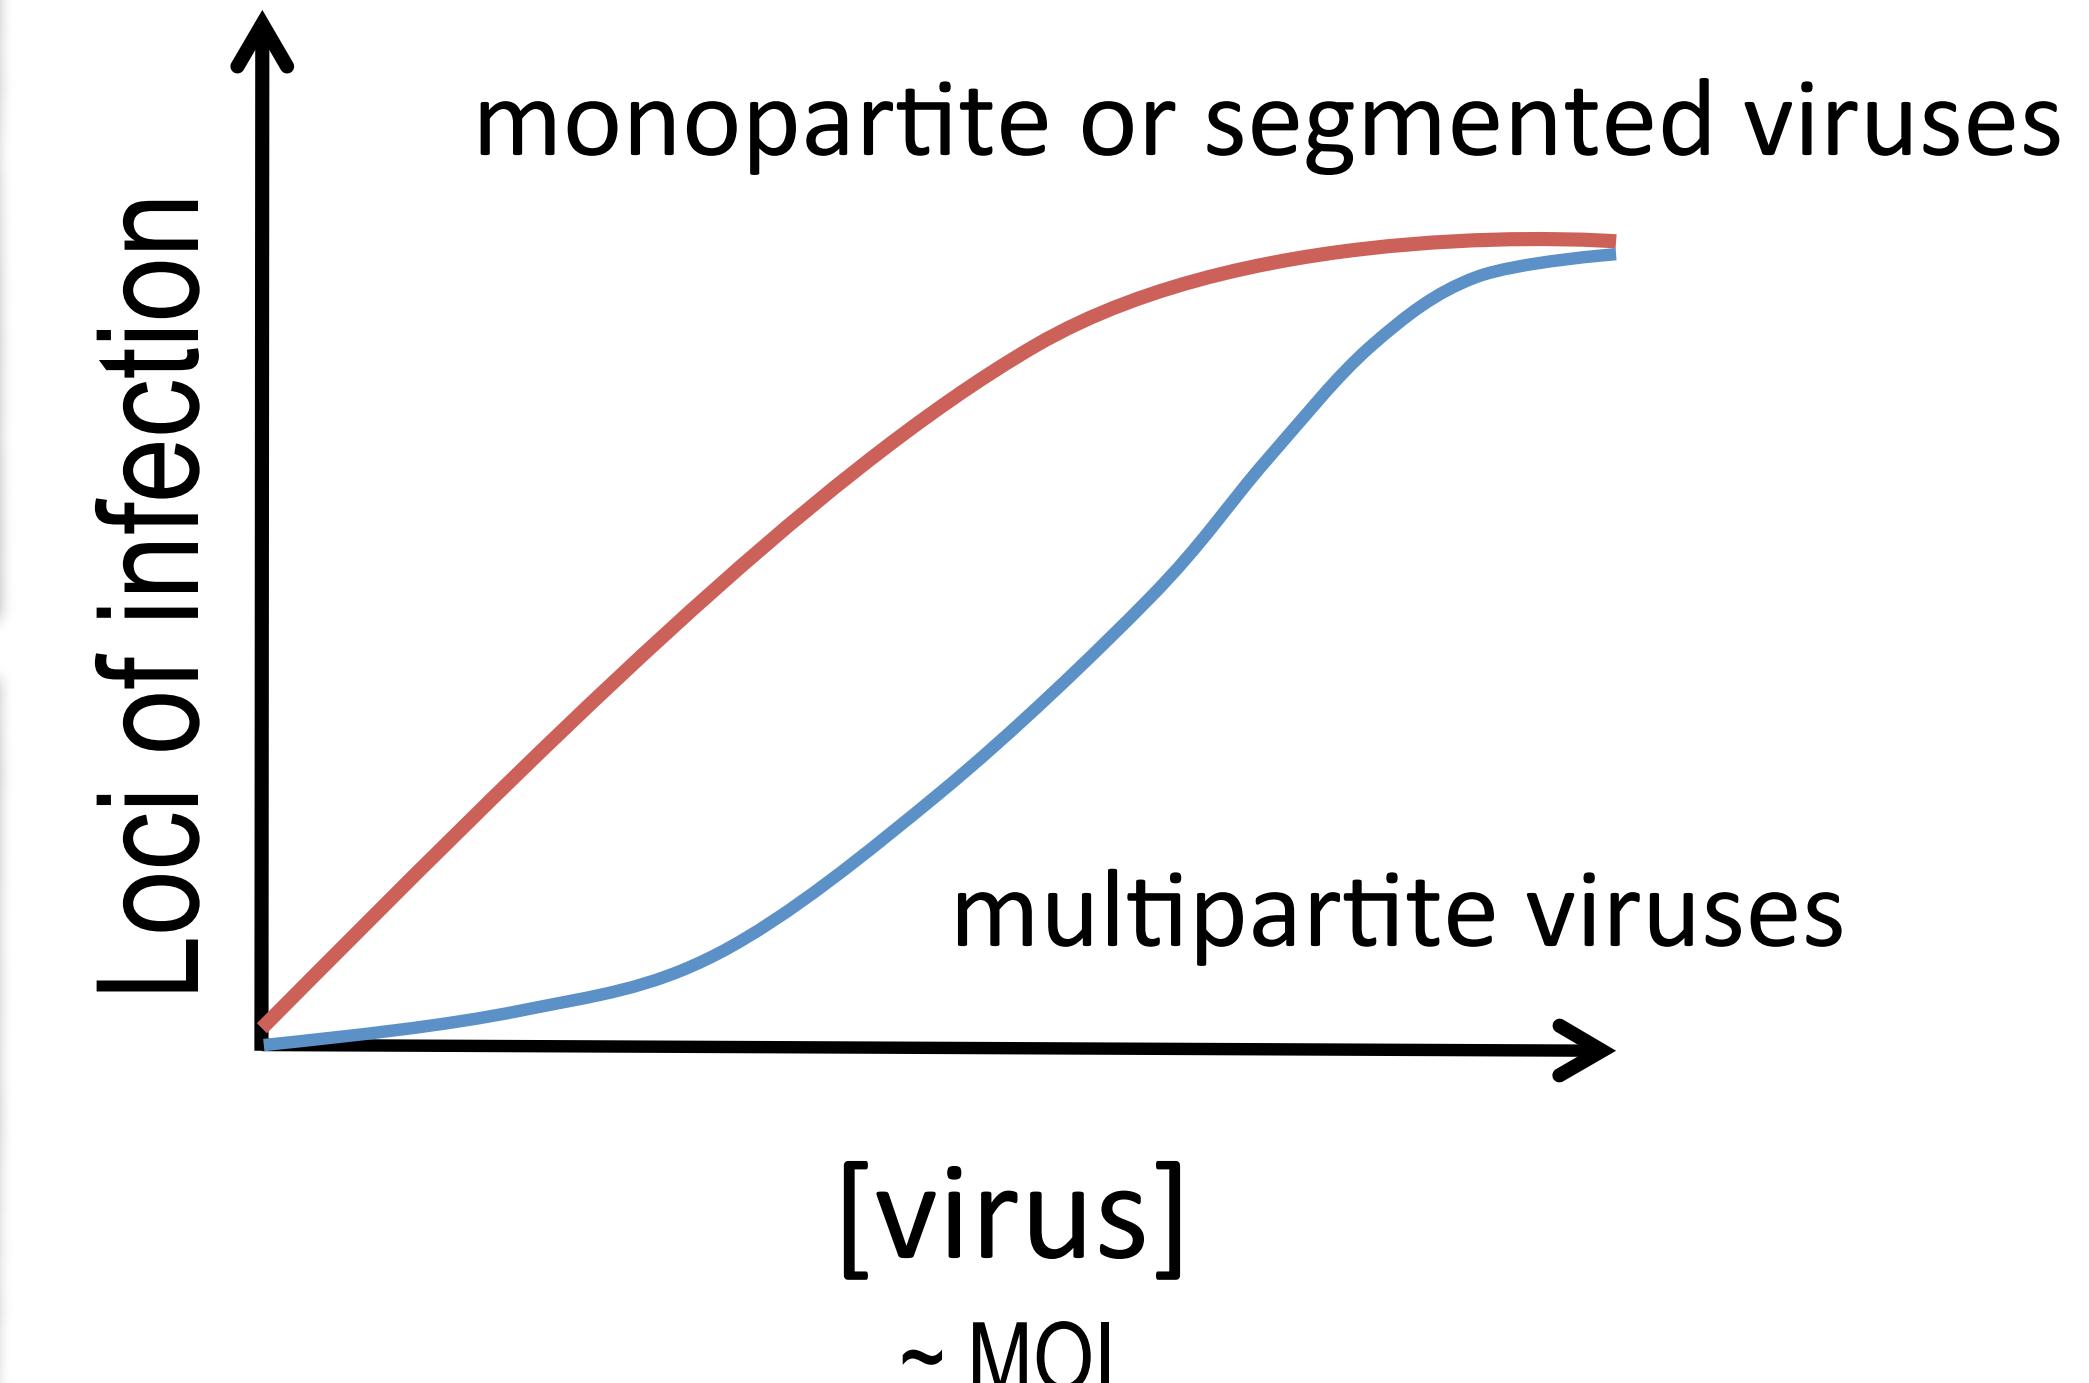

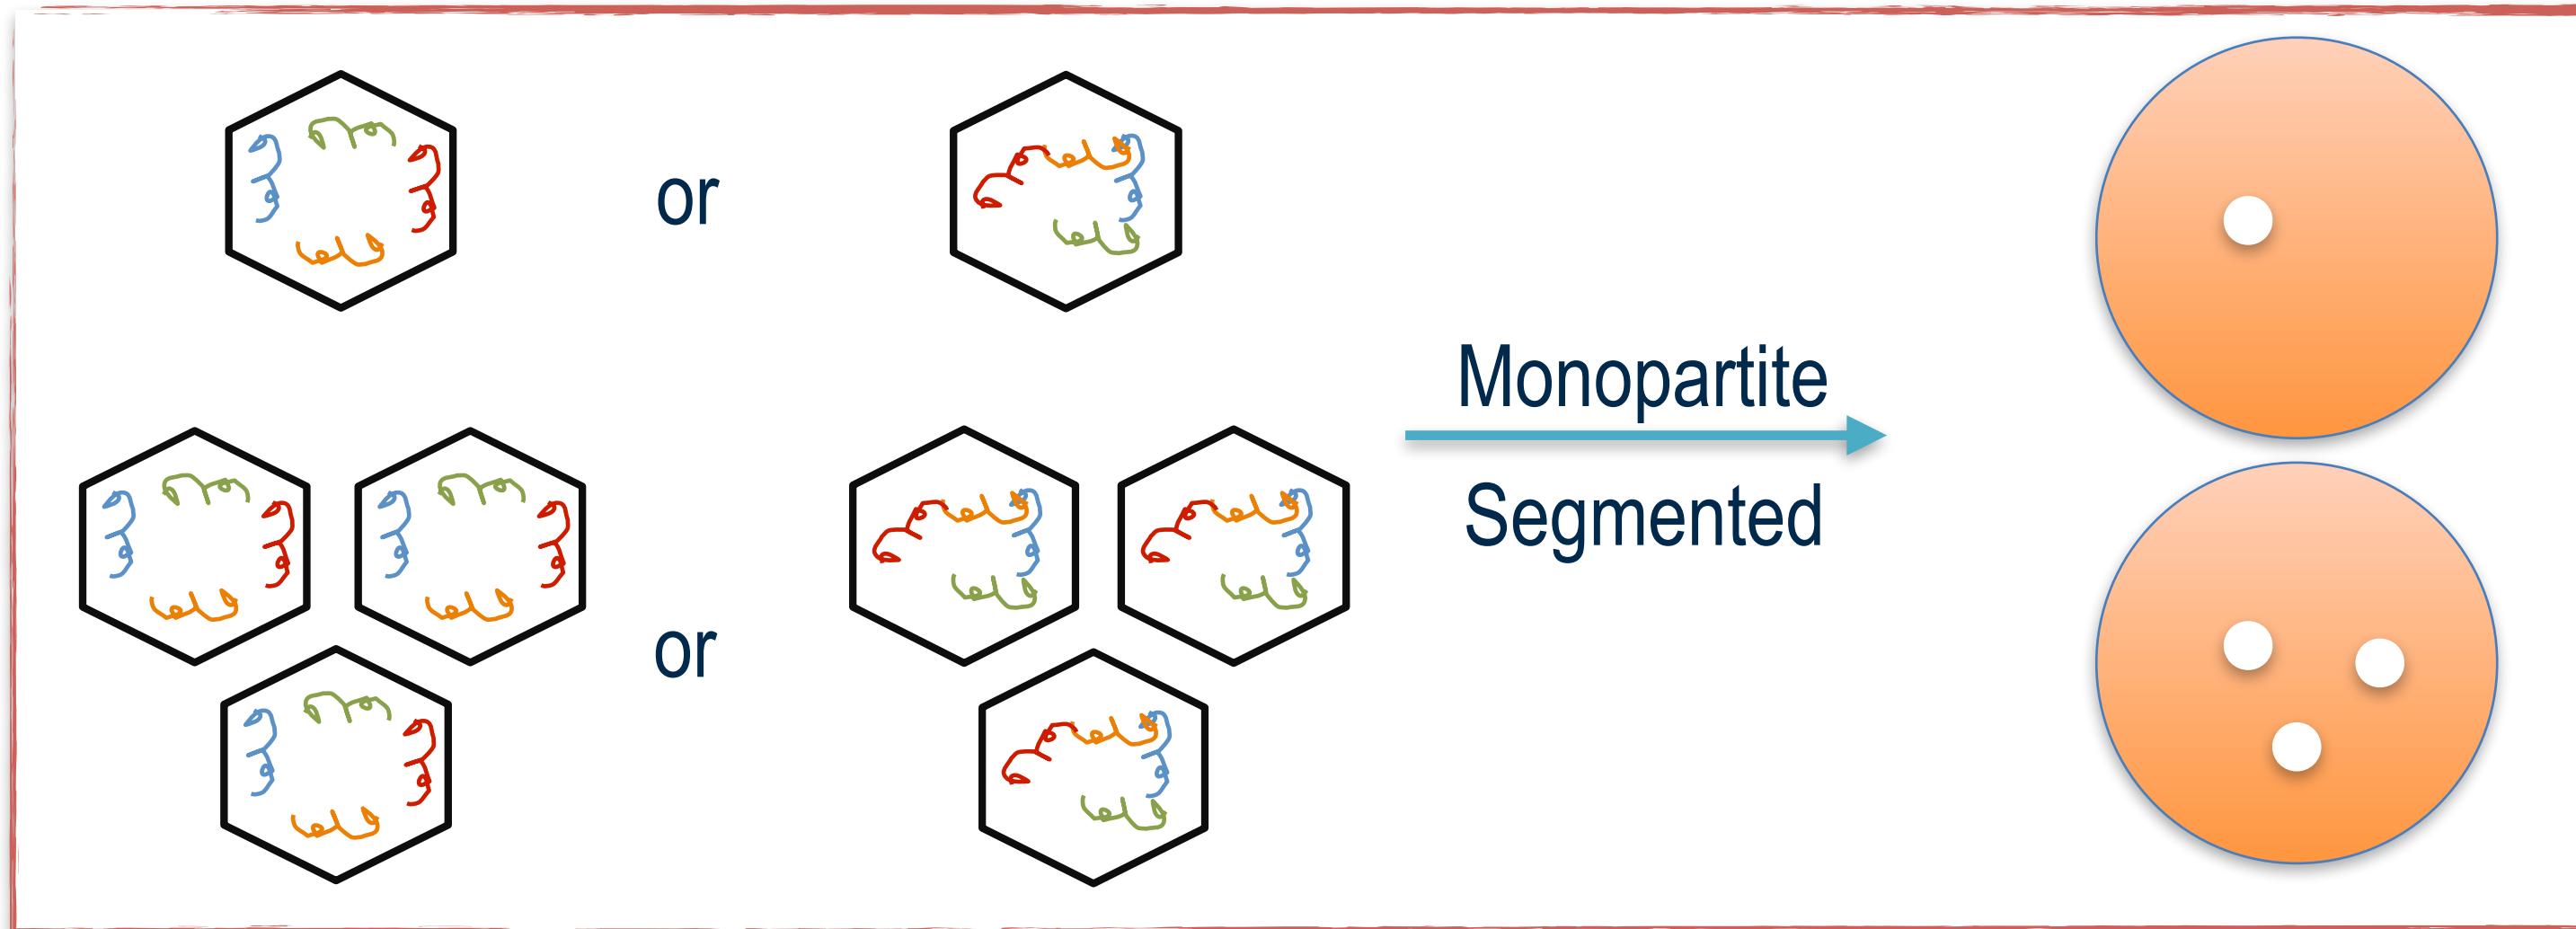

or

e.g. Nanoviridae (6 to 8)

e.g. Beet necrotic yellow vein virus (4 to 5)

One full genome / One infection

Benefits vs Costs

Viral genome = fixed number of each gene

Replication cycle : « cell autonomous » and spread to neighbour cells

Adaptation to environment through sequence mutation(s)

Replication time

10 kb

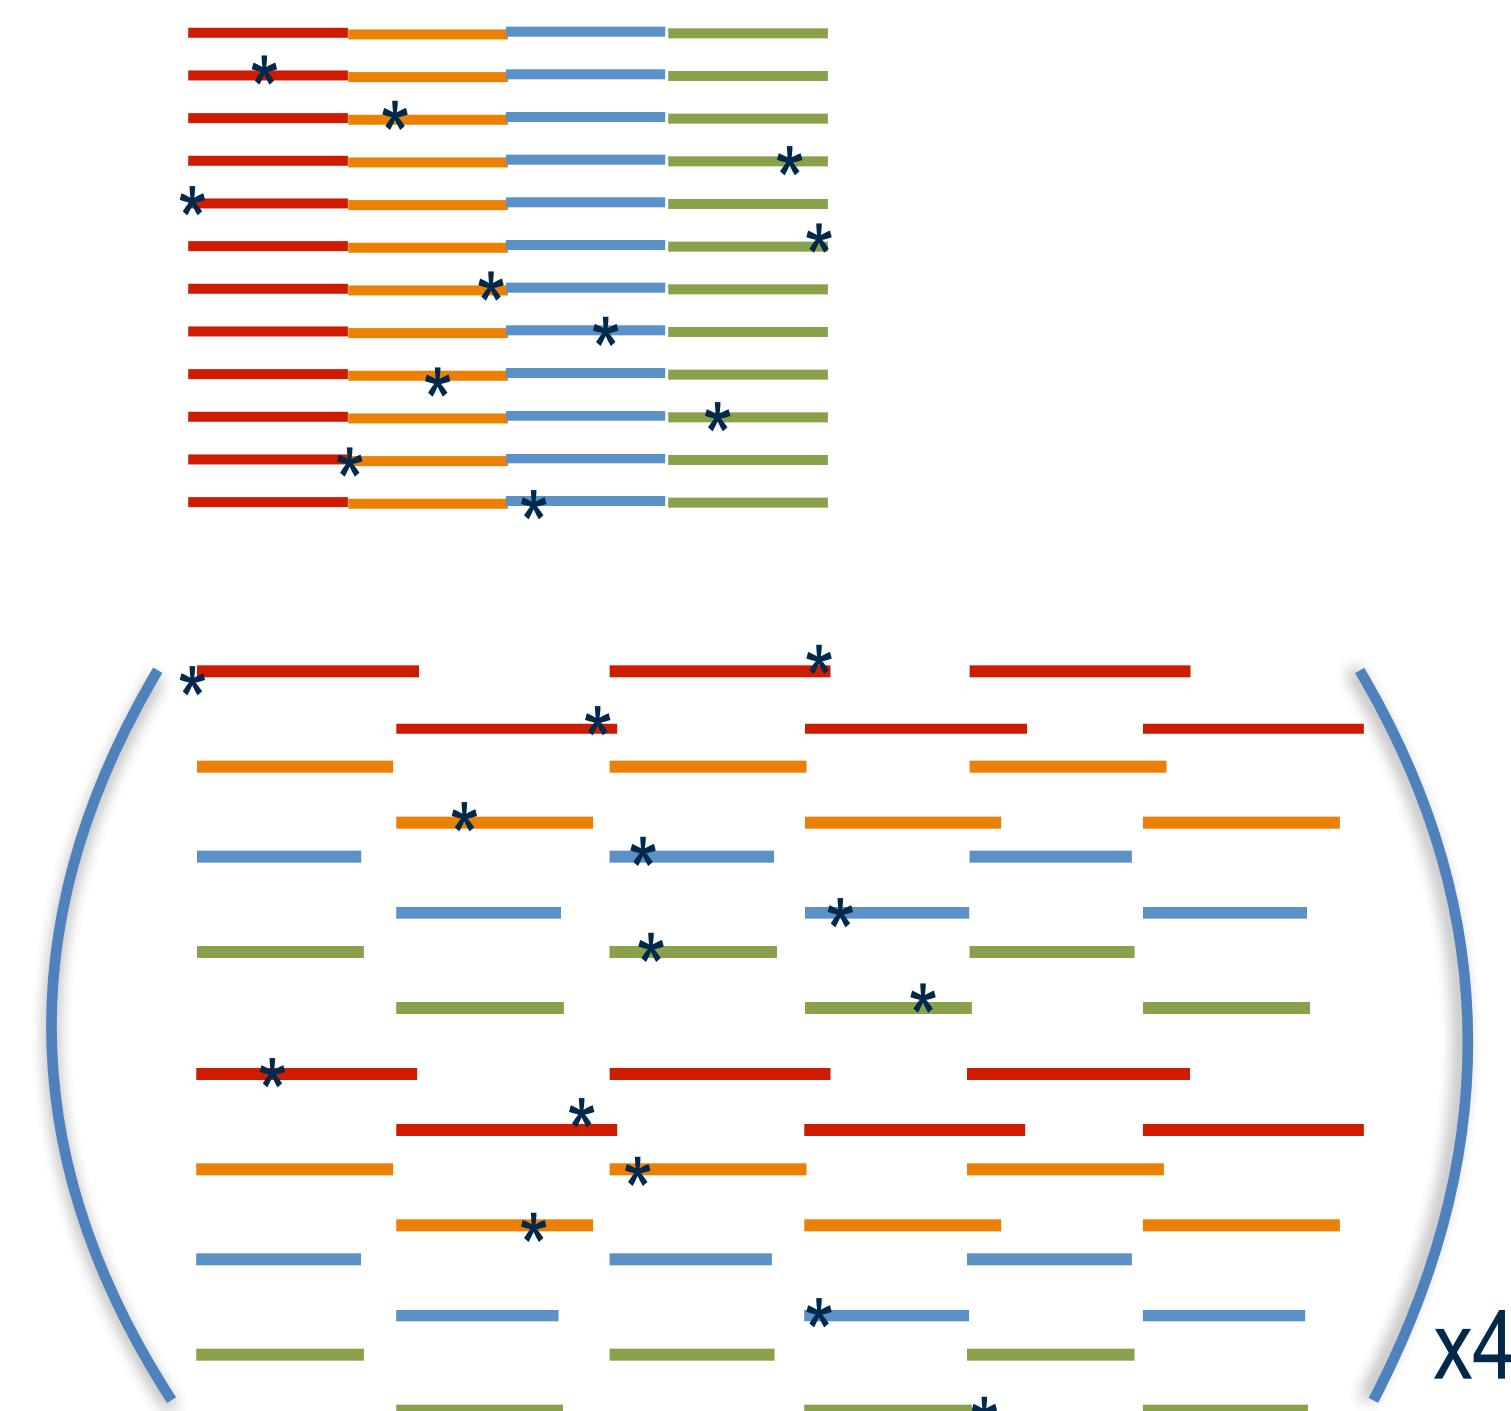

* mutation rate $\sim 10^{-4}$

$\Sigma 10 \text{ kb}$

Replication time $\div 4$

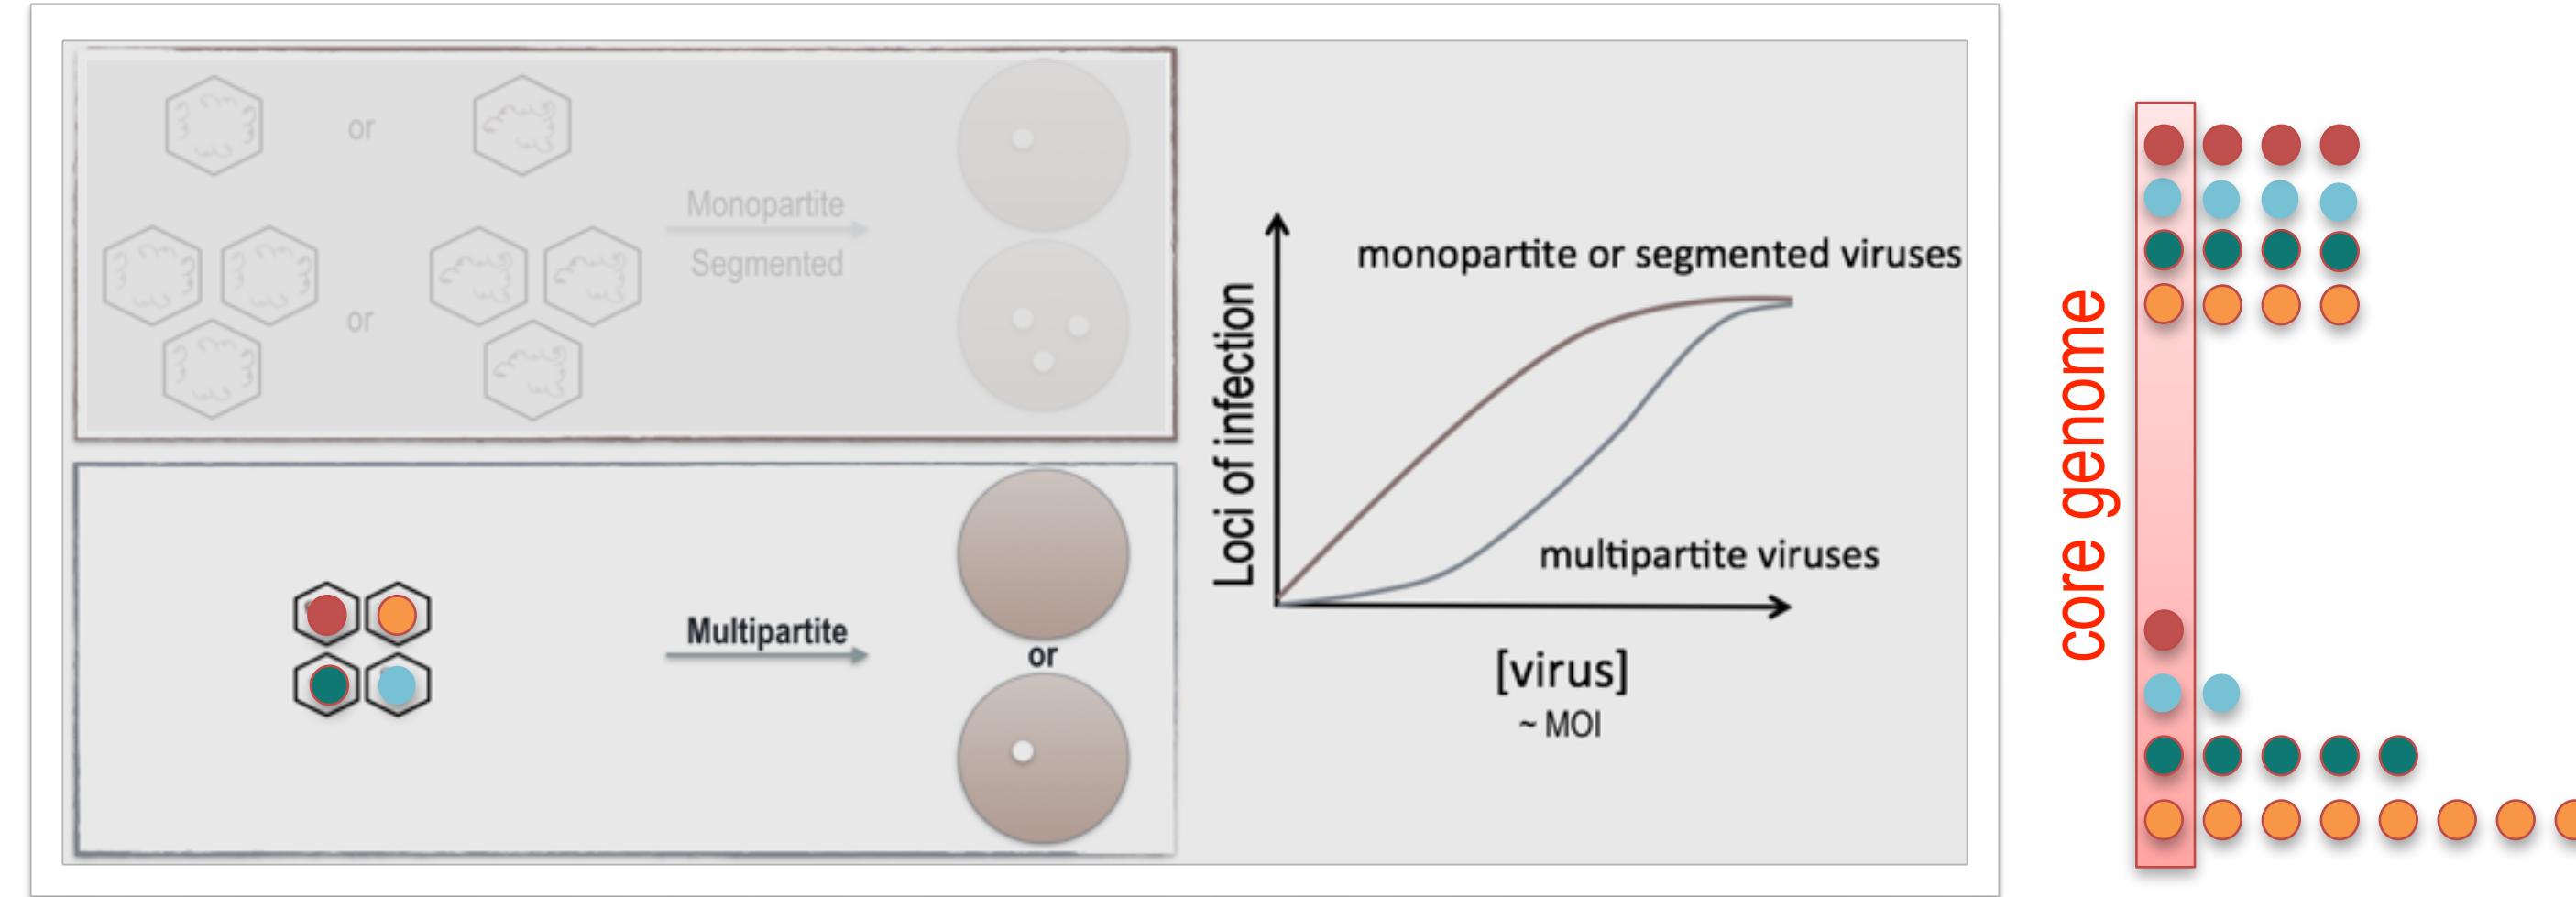

Genetic exchange
requires
recombination

Genetic exchange
favoured by segment
reassortment

Costs for multipartite viruses : what is the minimum ?

Probability of **infection decreases** with the number of genomic segments
and further decreases with unequal frequencies

equal frequencies
max ~ 4

unequal frequencies
max ~ 1

~~Virion stability~~
~~Replication time~~
Advantages are not dependant on frequencies
* mutation escape
Favoured exchange

The different genomic segments should « accumulate » to equal frequencies for a minimal cost

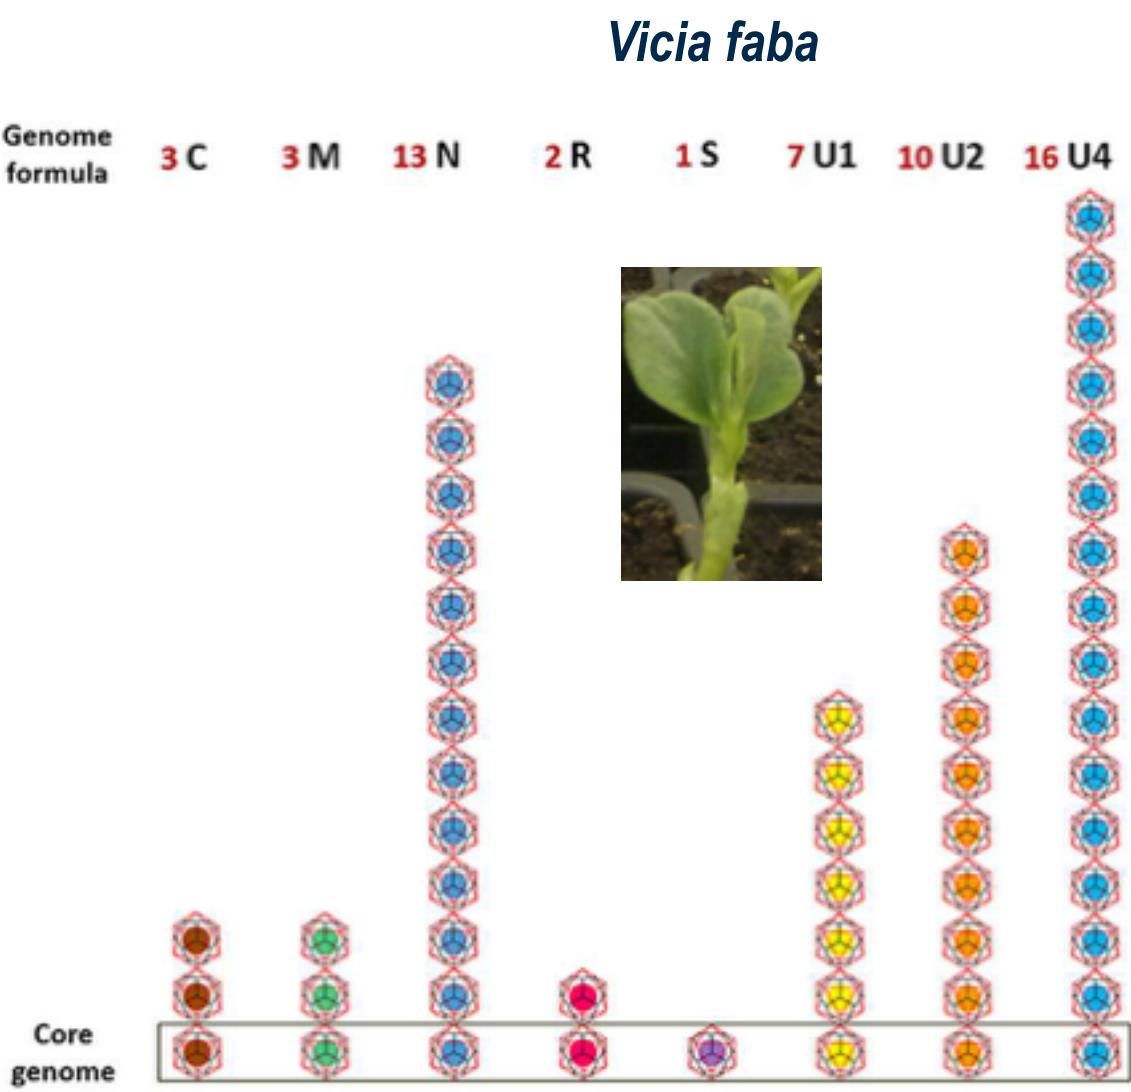

Gene-accordions // (gene) segment frequency variation: convergent regulatory/adaptative ?

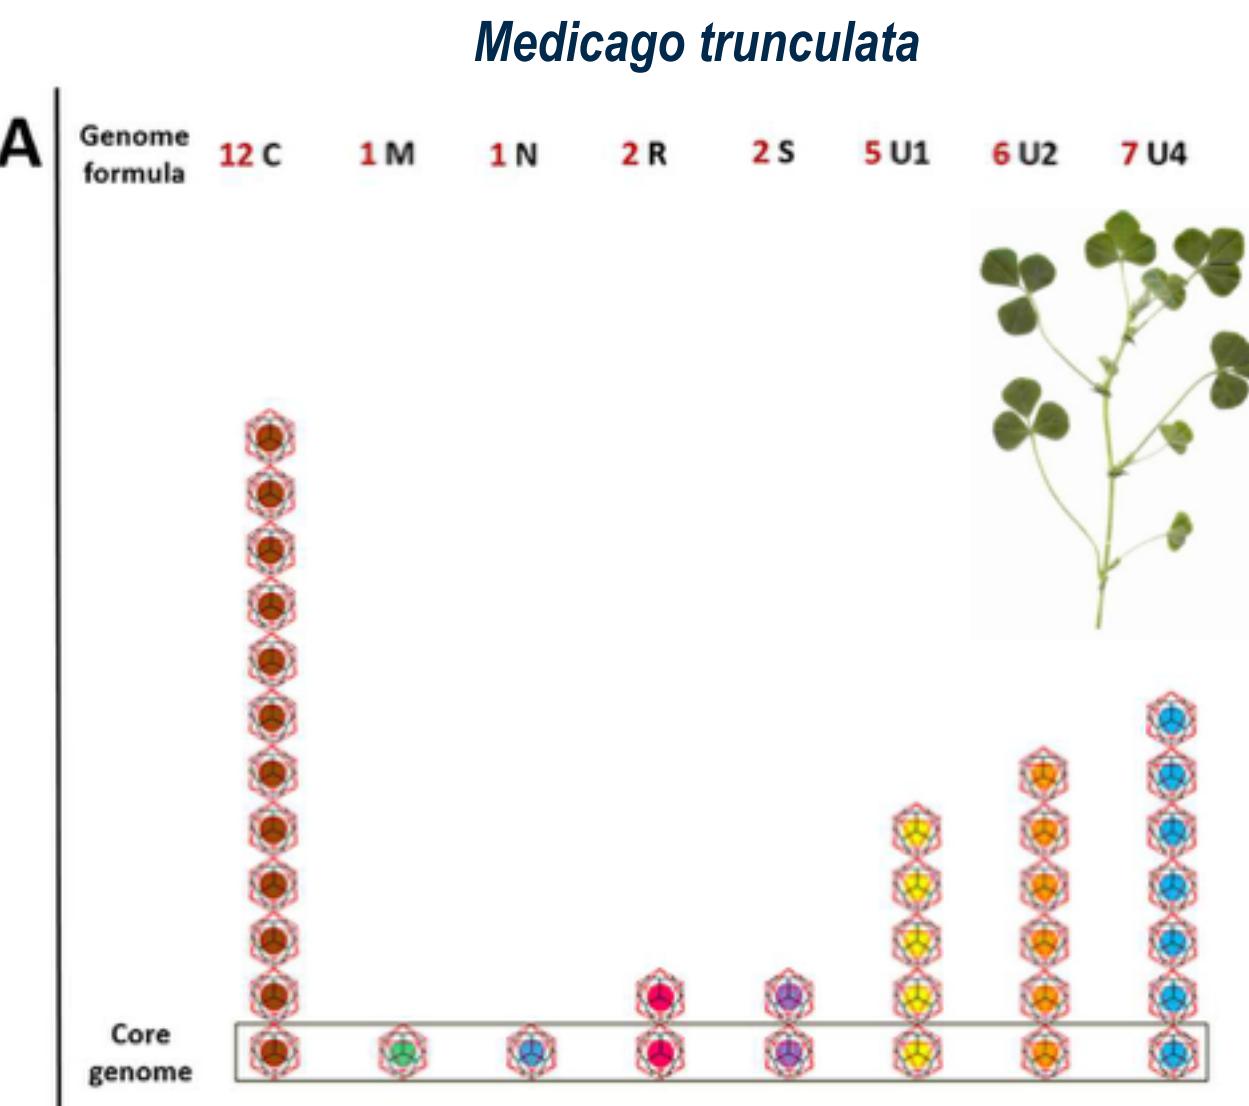

The Strange Lifestyle of Multipartite Viruses

Poxviruses Deploy Genomic Accordions to Adapt Rapidly against Host Antiviral Defenses

Nels C. Elde,^{1,4,*} Stephanie J. Child,² Michael T. Eickbush,¹ Jacob O. Kitzman,⁵ Kelsey Adam P. Geballe,^{2,3,6,7} and Harmit S. Malik^{1,8,*}

In contrast to RNA viruses, double-stranded DNA viruses have low mutation rates yet must still adapt rapidly in response to changing host defenses. To determine mechanisms of adaptation, we subjected the model poxvirus vaccinia to serial propagation in human cells, where its antihost factor K3L is maladapted against the antiviral protein kinase R (PKR). Viruses rapidly acquired higher fitness via recurrent K3L gene amplifications, incurring up to 7%–10% increases in genome size. These transient gene expansions were necessary and sufficient to counteract human PKR and facilitated the gain of an adaptive amino acid substitution in K3L that also defeats PKR. Subsequent reductions in gene amplifications offset the costs associated with larger genome size while retaining adaptive substitutions. Our discovery of viral “gene-accordions” explains how poxviruses can rapidly adapt to defeat different host defenses despite low mutation rates and reveals how classical Red Queen conflicts can progress through unrecognized intermediates.

Quantitative analysis of gene amplification in insecticide-resistant *Culex* mosquitoes

Michael G. PATON, S. H. P. Parakrama KARUNARATNE, Elsa GIAKOUIMAKI, Neil ROBERTS and Janet HEMINGWAY¹
School of Biosciences, University of Wales Cardiff, P.O. Box 915, Cardiff CF1 3TL, U.K.

The amplification of carboxylesterase structural genes followed by their overexpression is the most common mechanism of resistance to organophosphorus insecticides in *Culex* mosquitoes. Most resistant *Culex quinquefasciatus* mosquitoes have co-amplified *estα2¹* and *estβ2¹* genes. Recently, Southern, DNA dot-

Beet necrotic yellow vein virus (BNYVV)

Most segmented genome among (+) strand RNA viruses
Multipartite virus
Each capped and poly-A viral genomic RNA individually packaged into distinct rod-shaped particles

The VIRUS

Benyviridae Benyvirus Beet necrotic yellow vein virus

The VECTOR

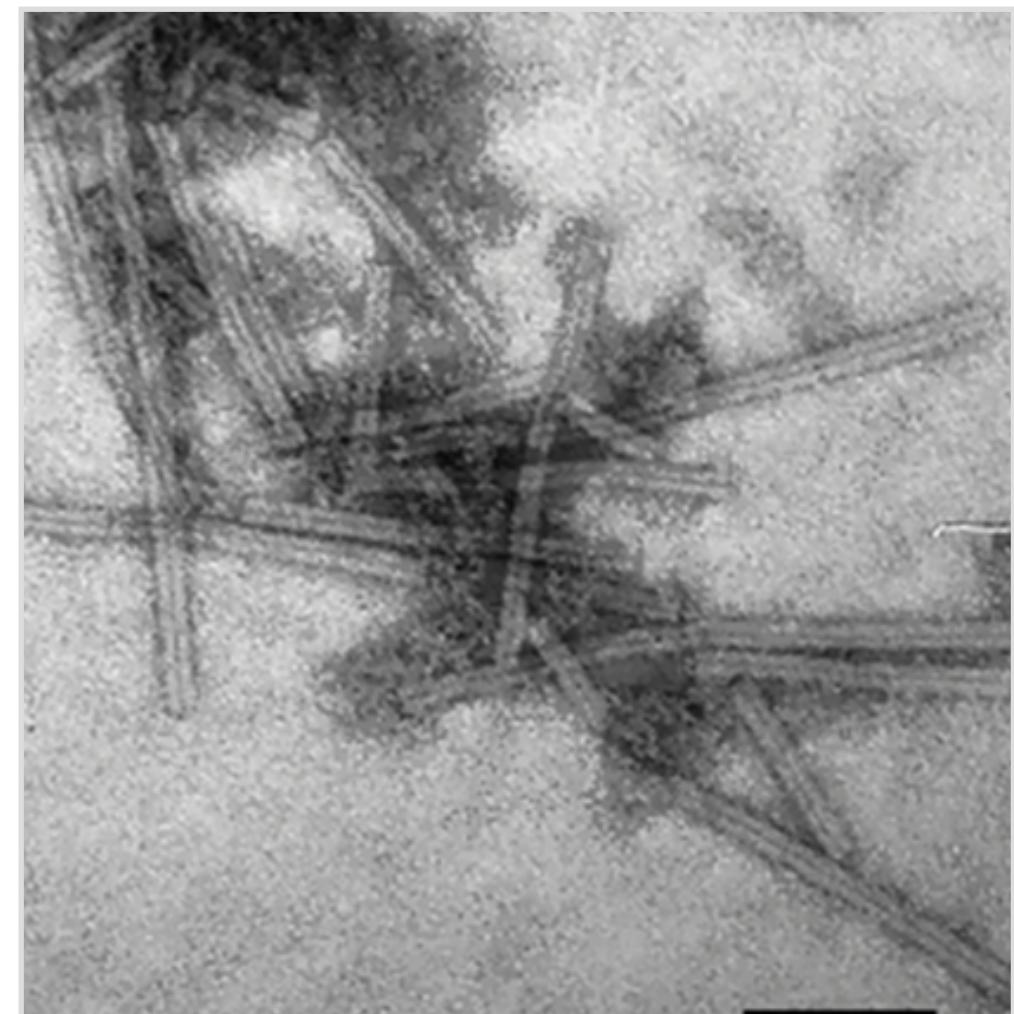

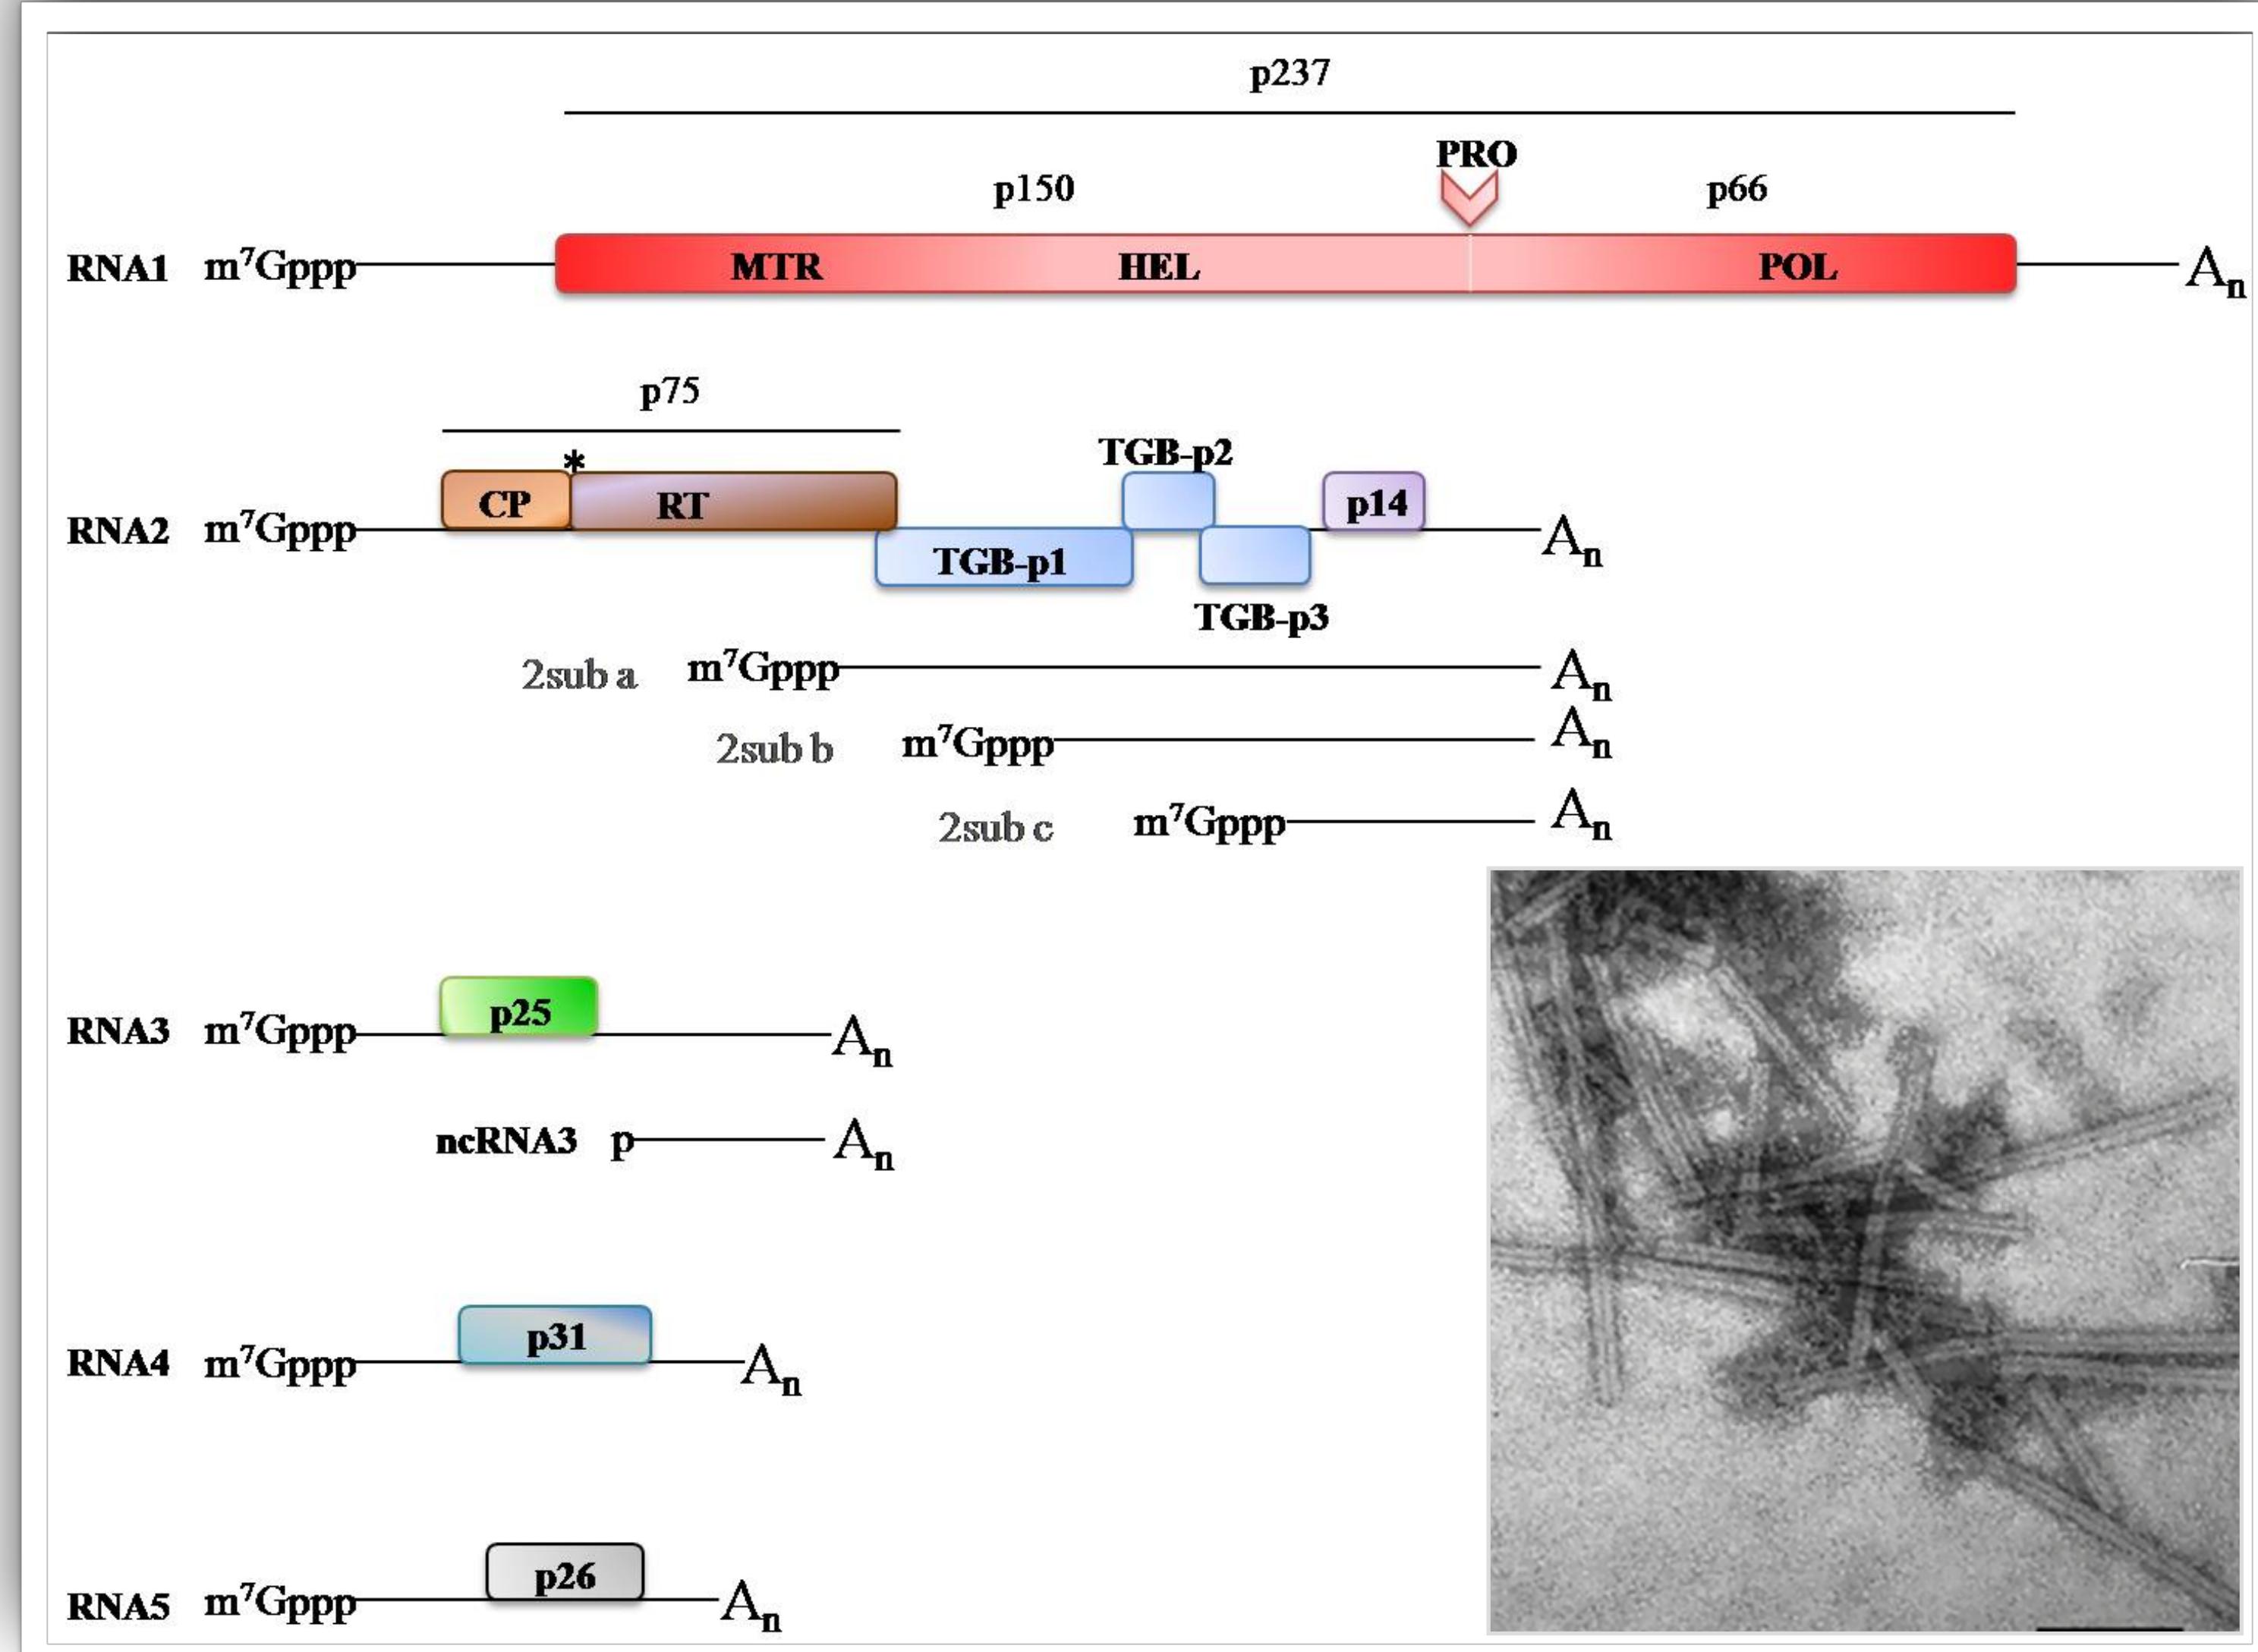

Polymyxa beta (Protozoa)

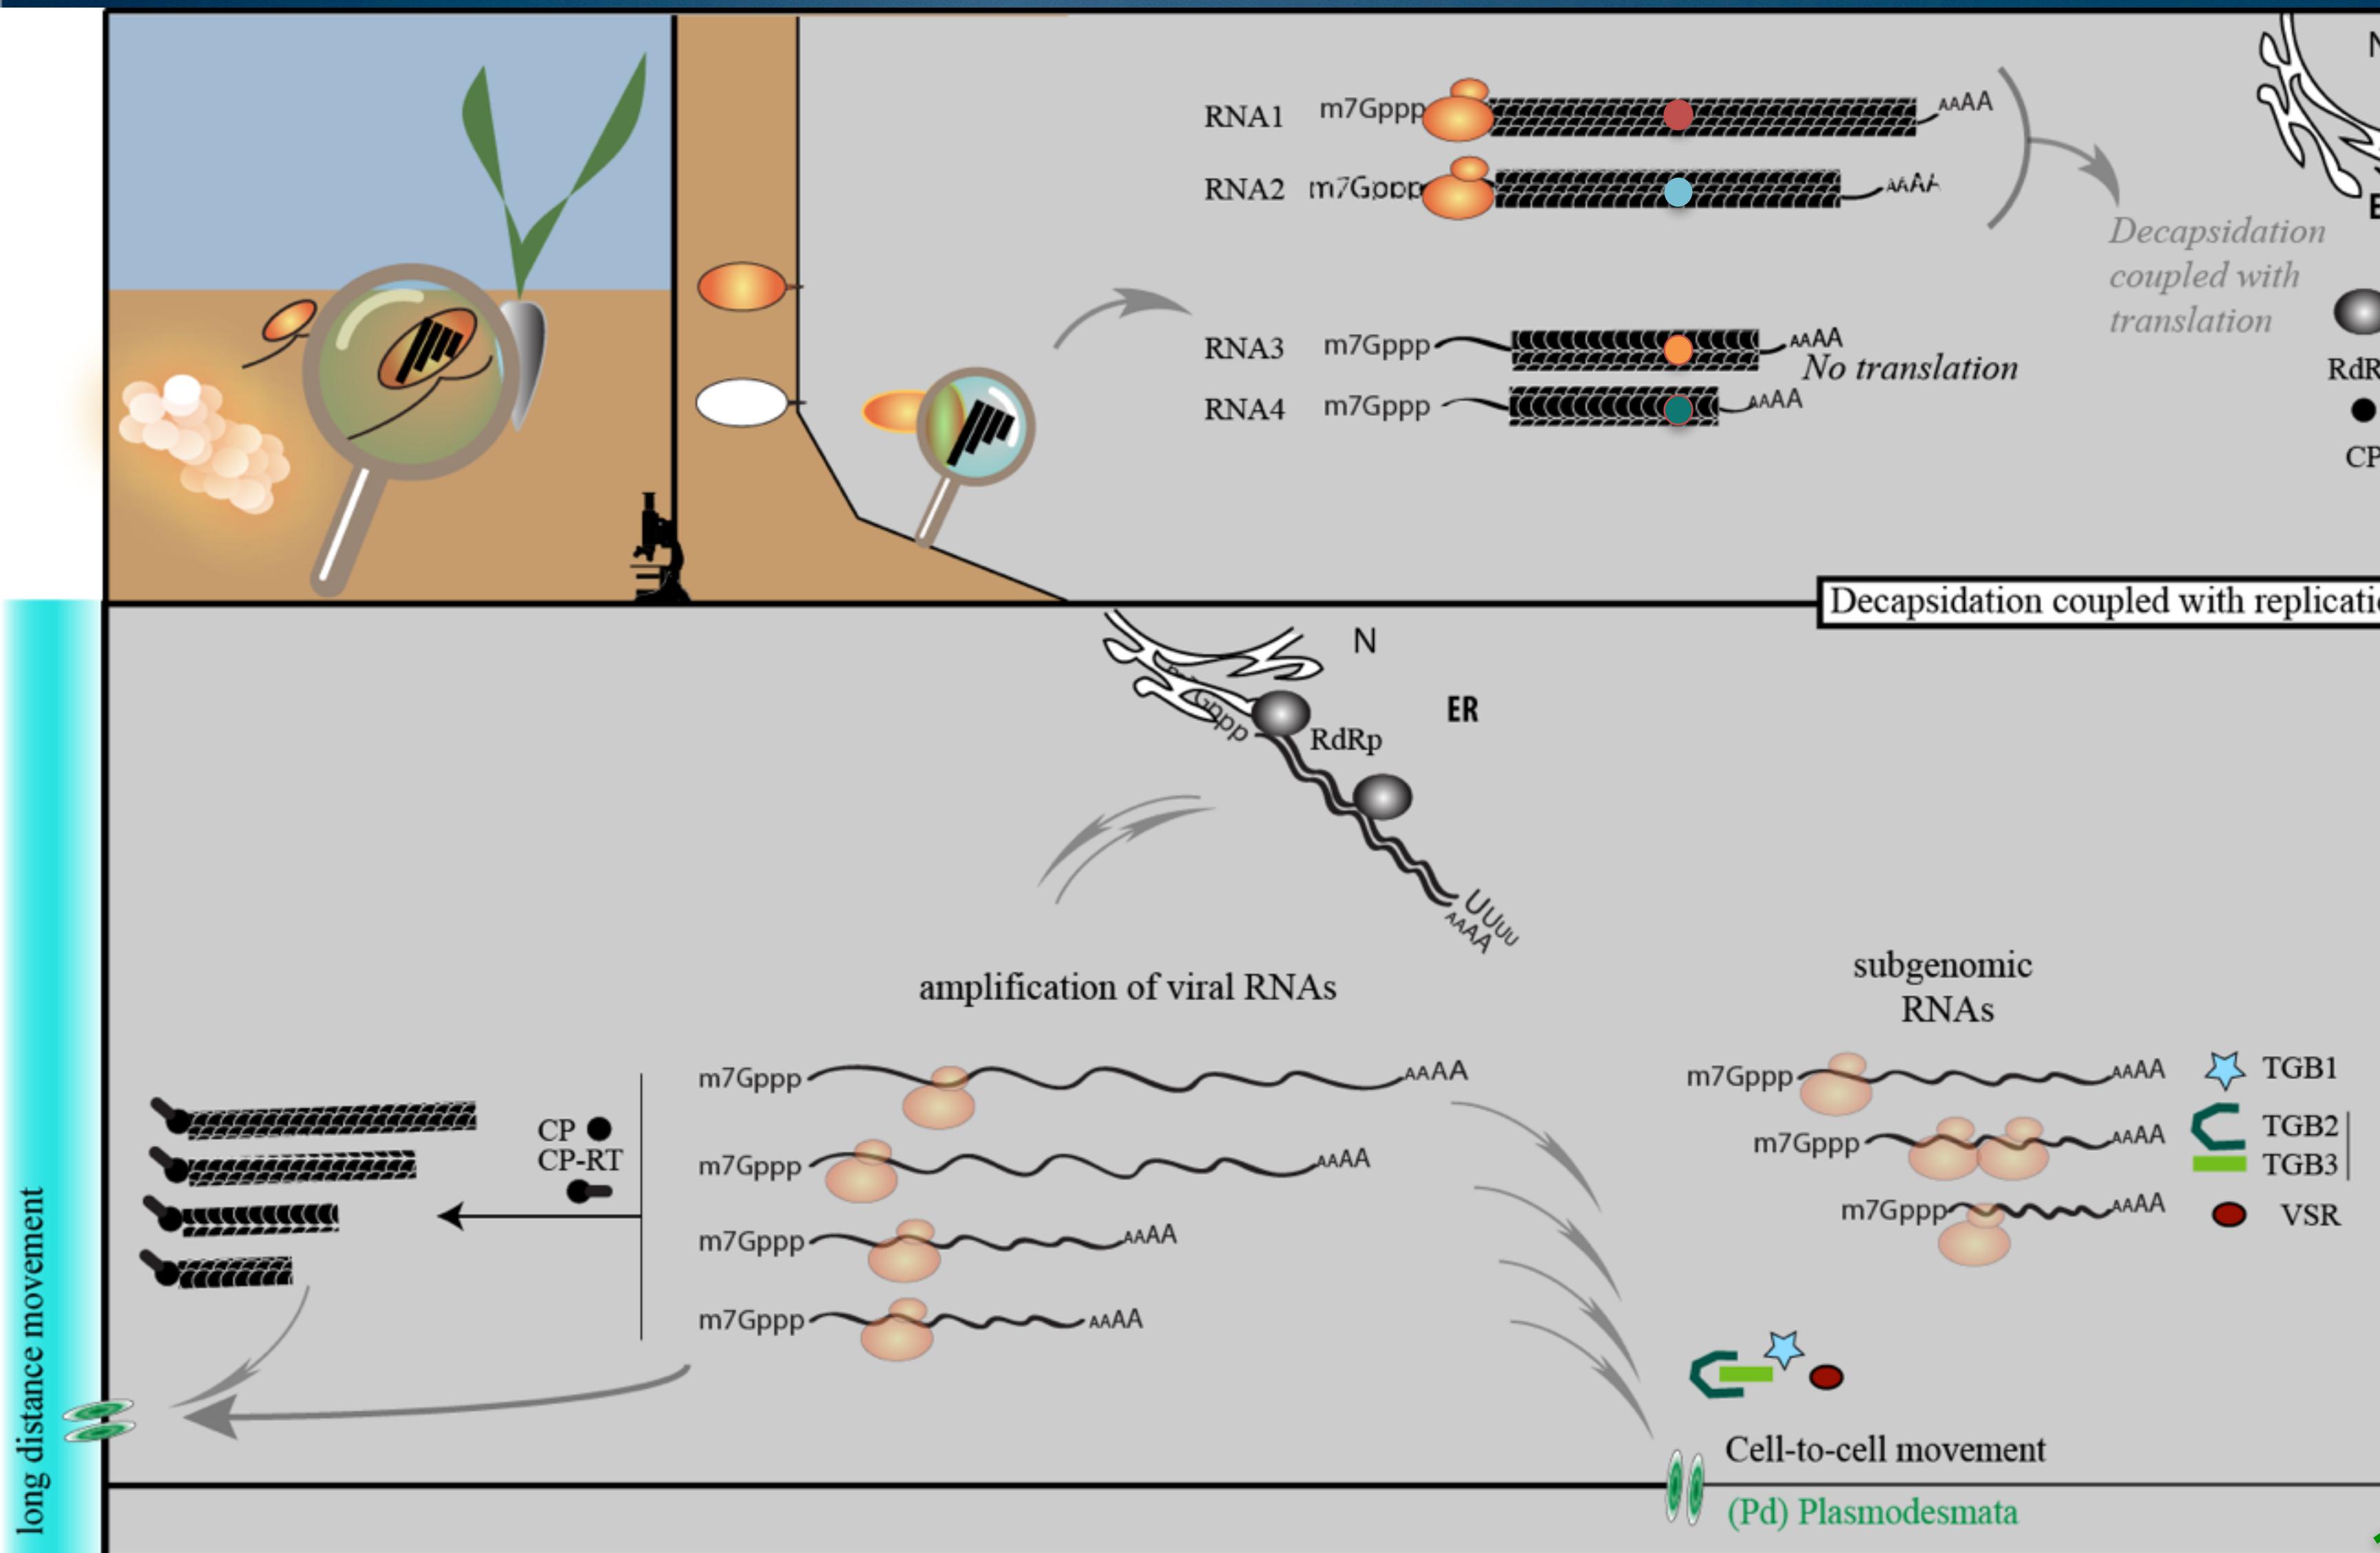

Beta vulgaris sp.

The HOST

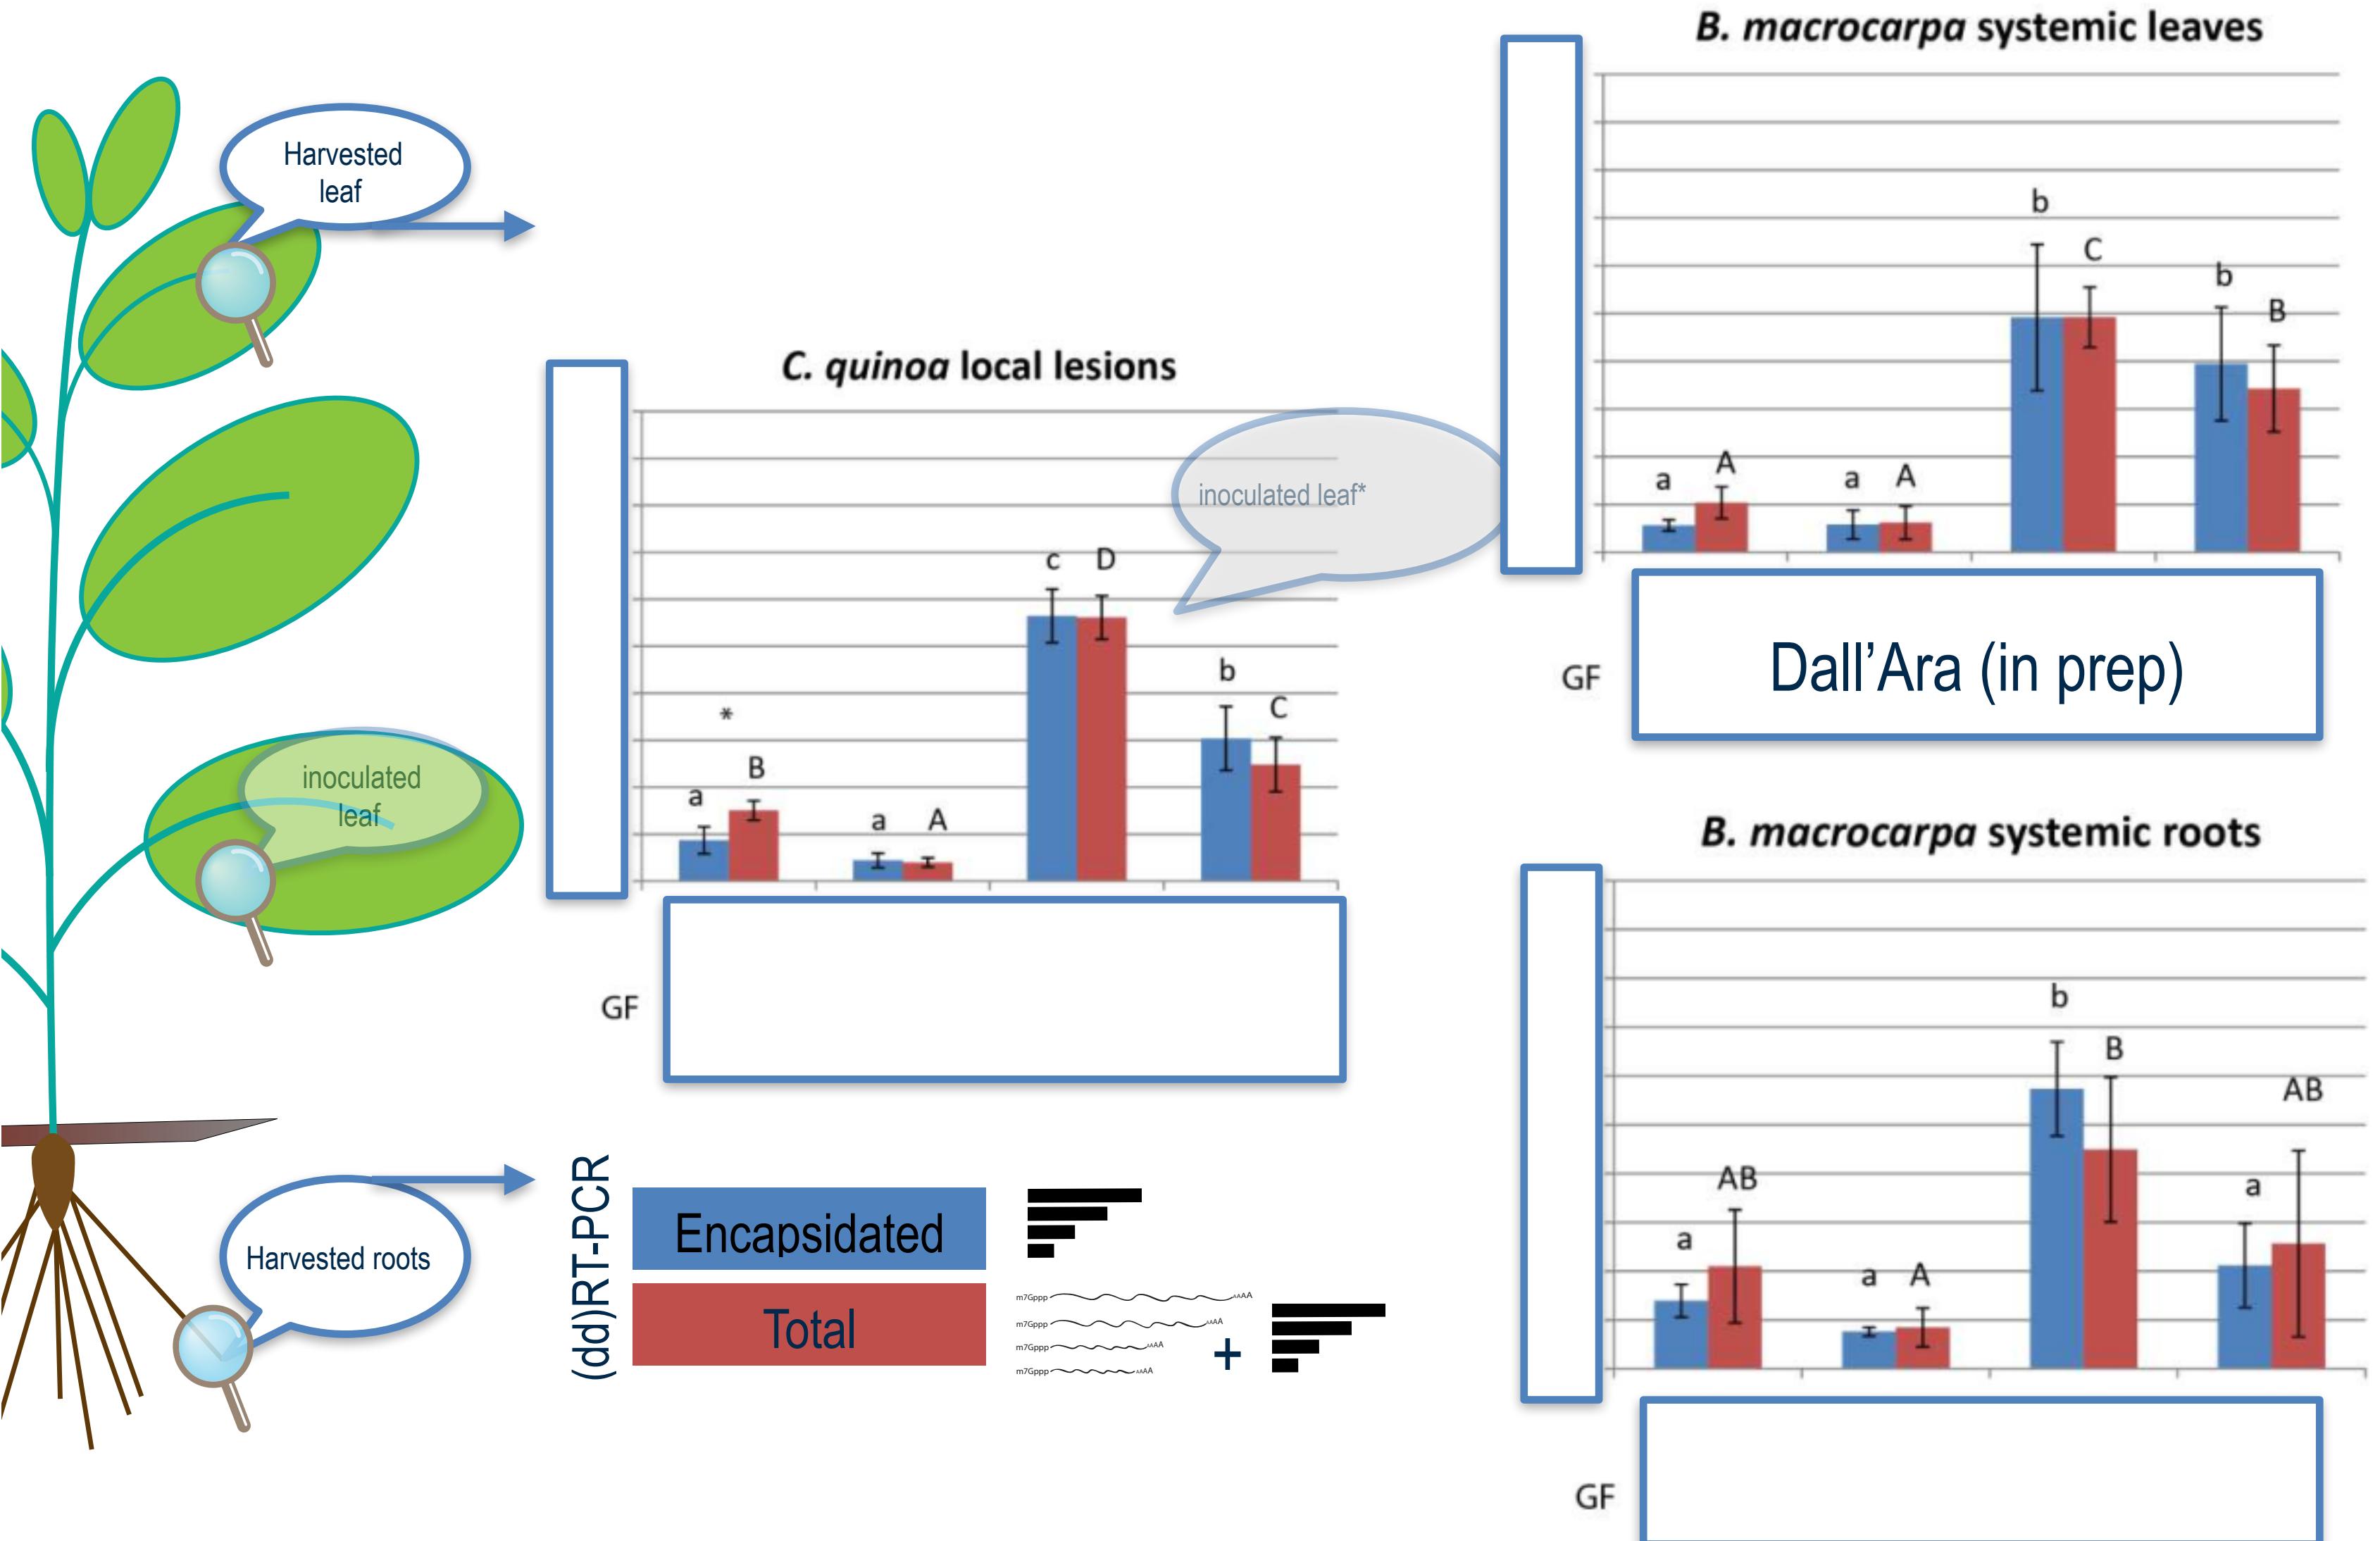

A 'textbook' view for a plant multipartite RNA lifecycle (e.g. BNYVV)

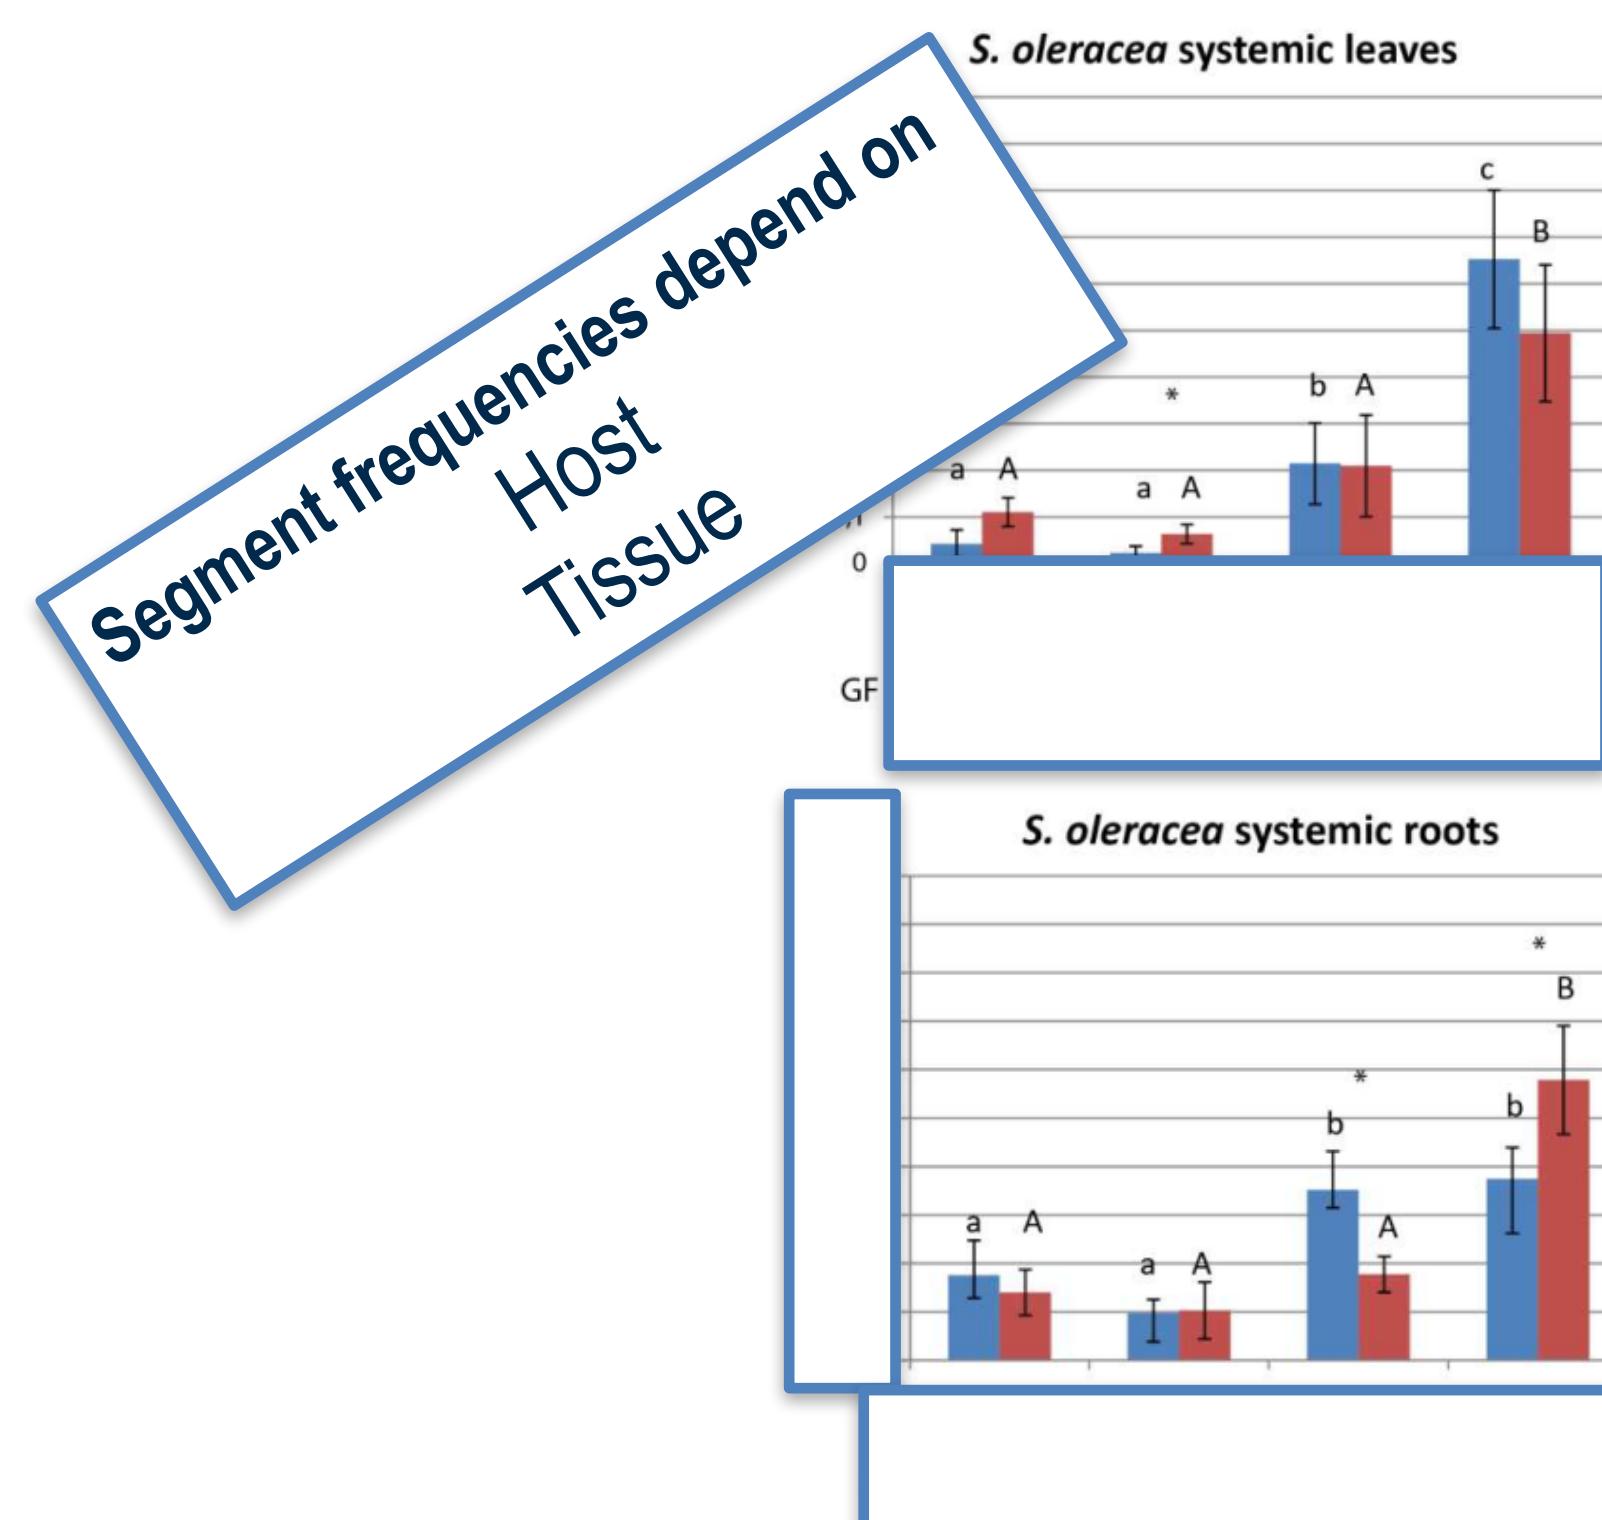

a Déjà vu impression

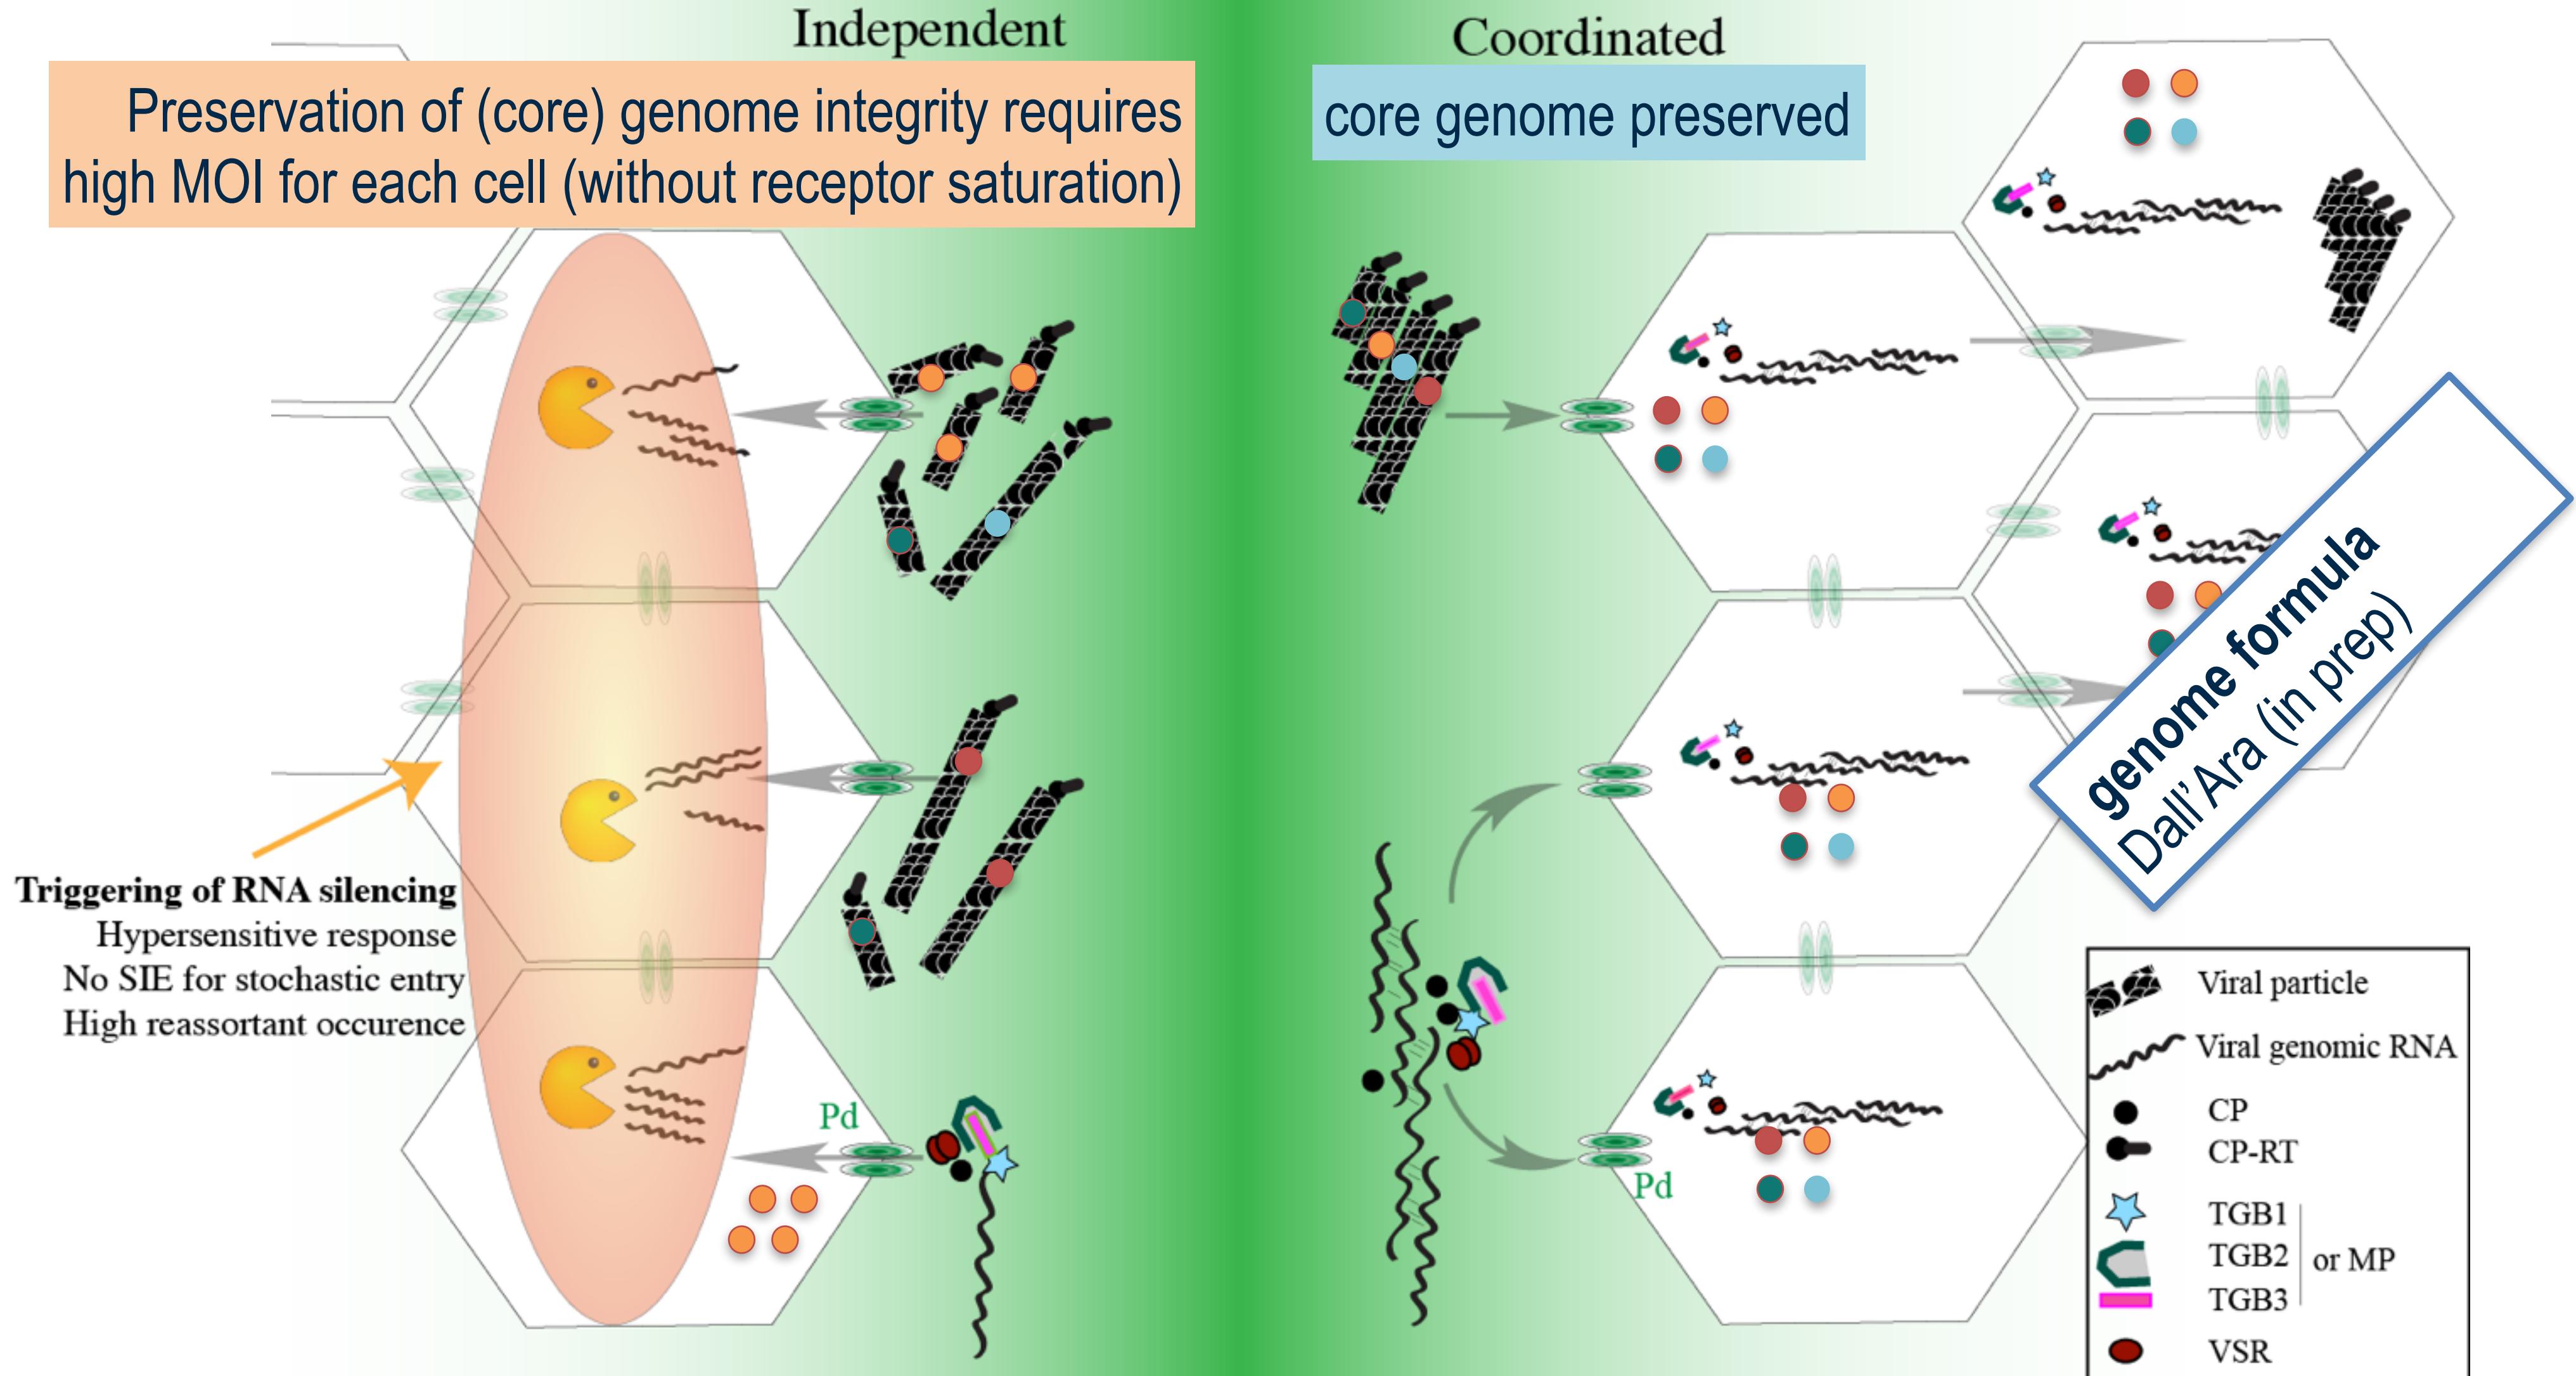

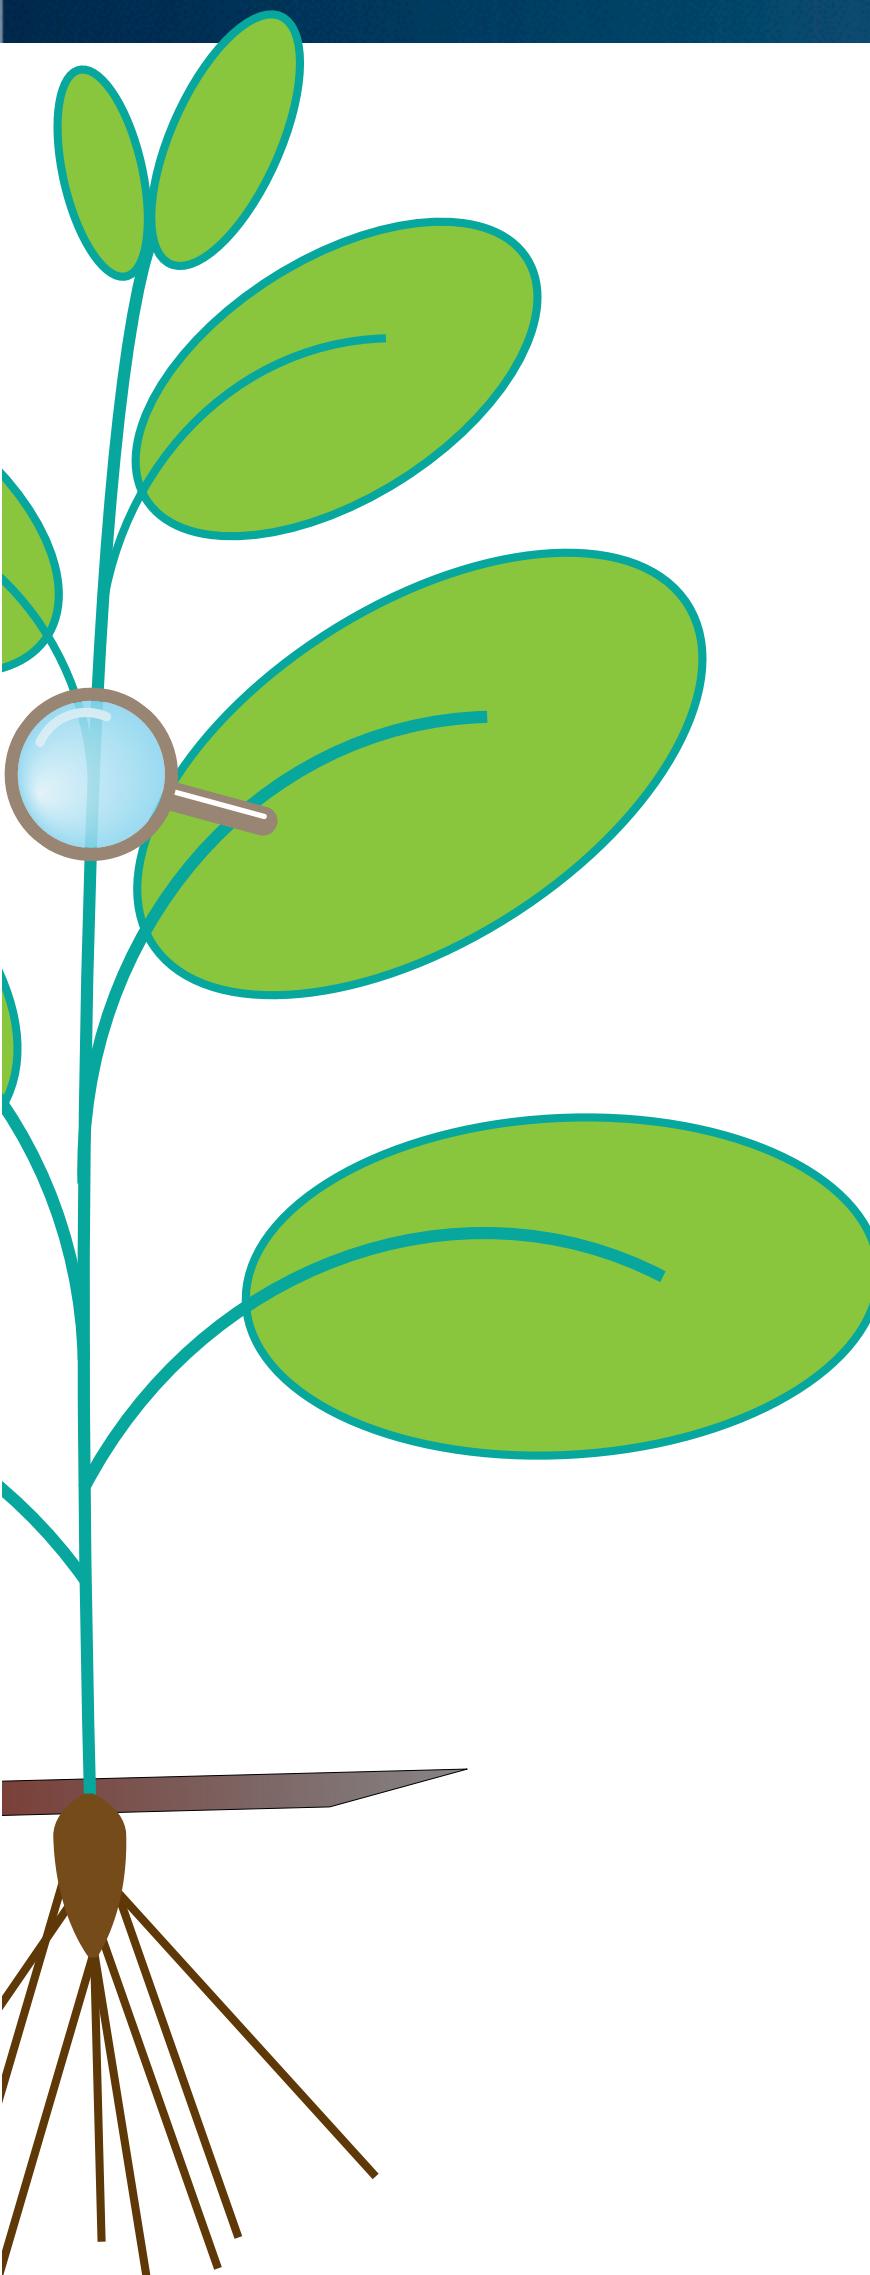

BNYVV segment **relative** frequencies in infected plant tissues

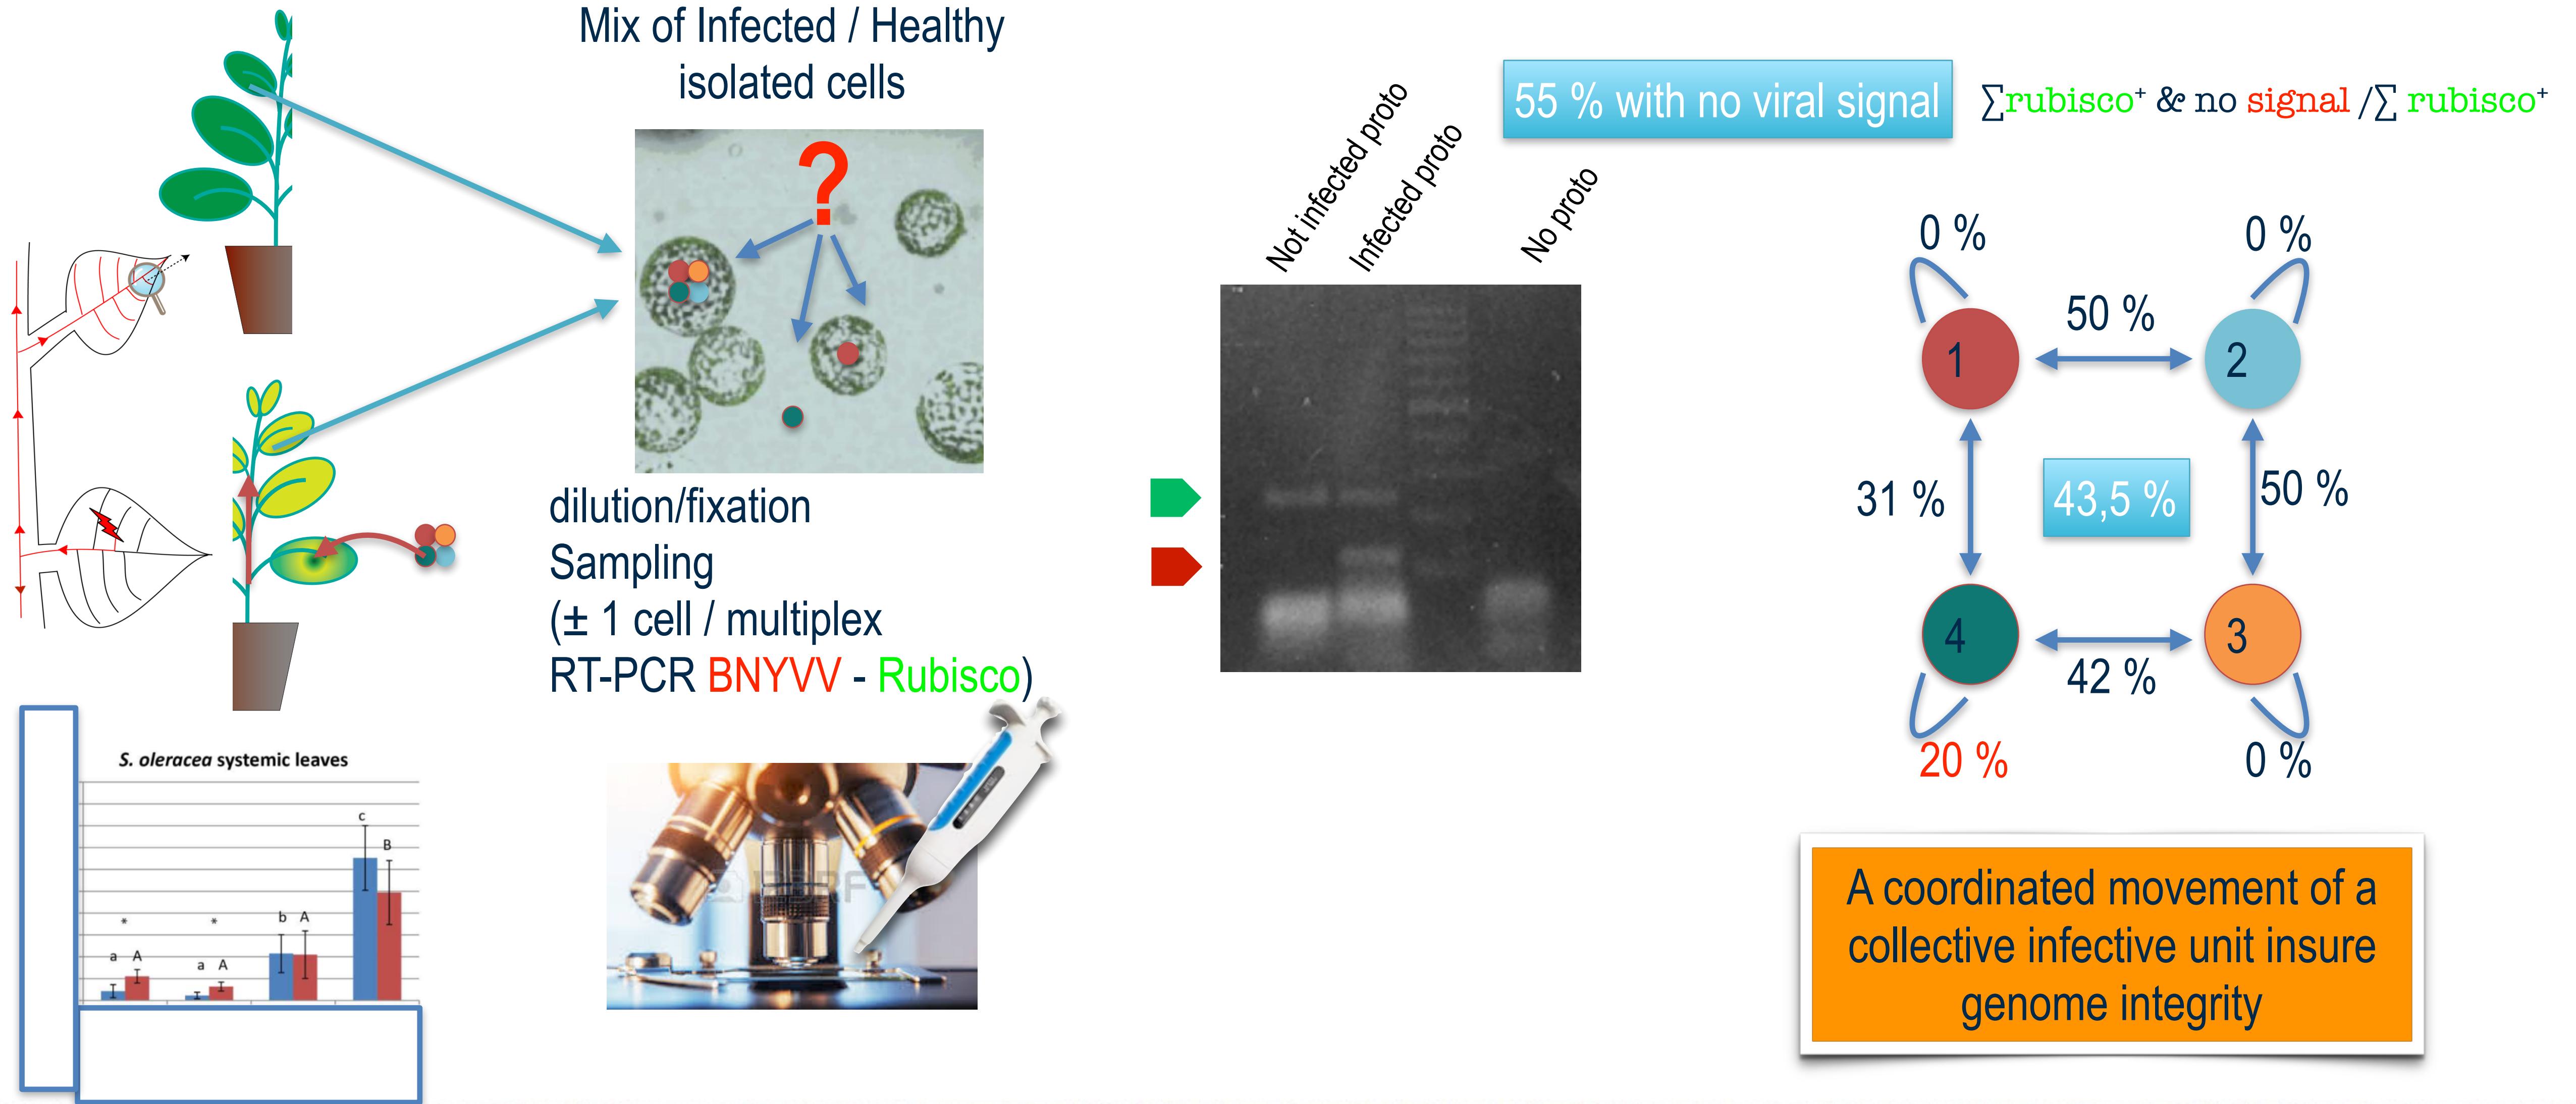

Segment frequencies differ
mean $\sim X^{\text{RNA1}}/Y^{\text{RNA2}}/Z^{\text{RNA3}}/A^{\text{RNA4}}$
= genome formula

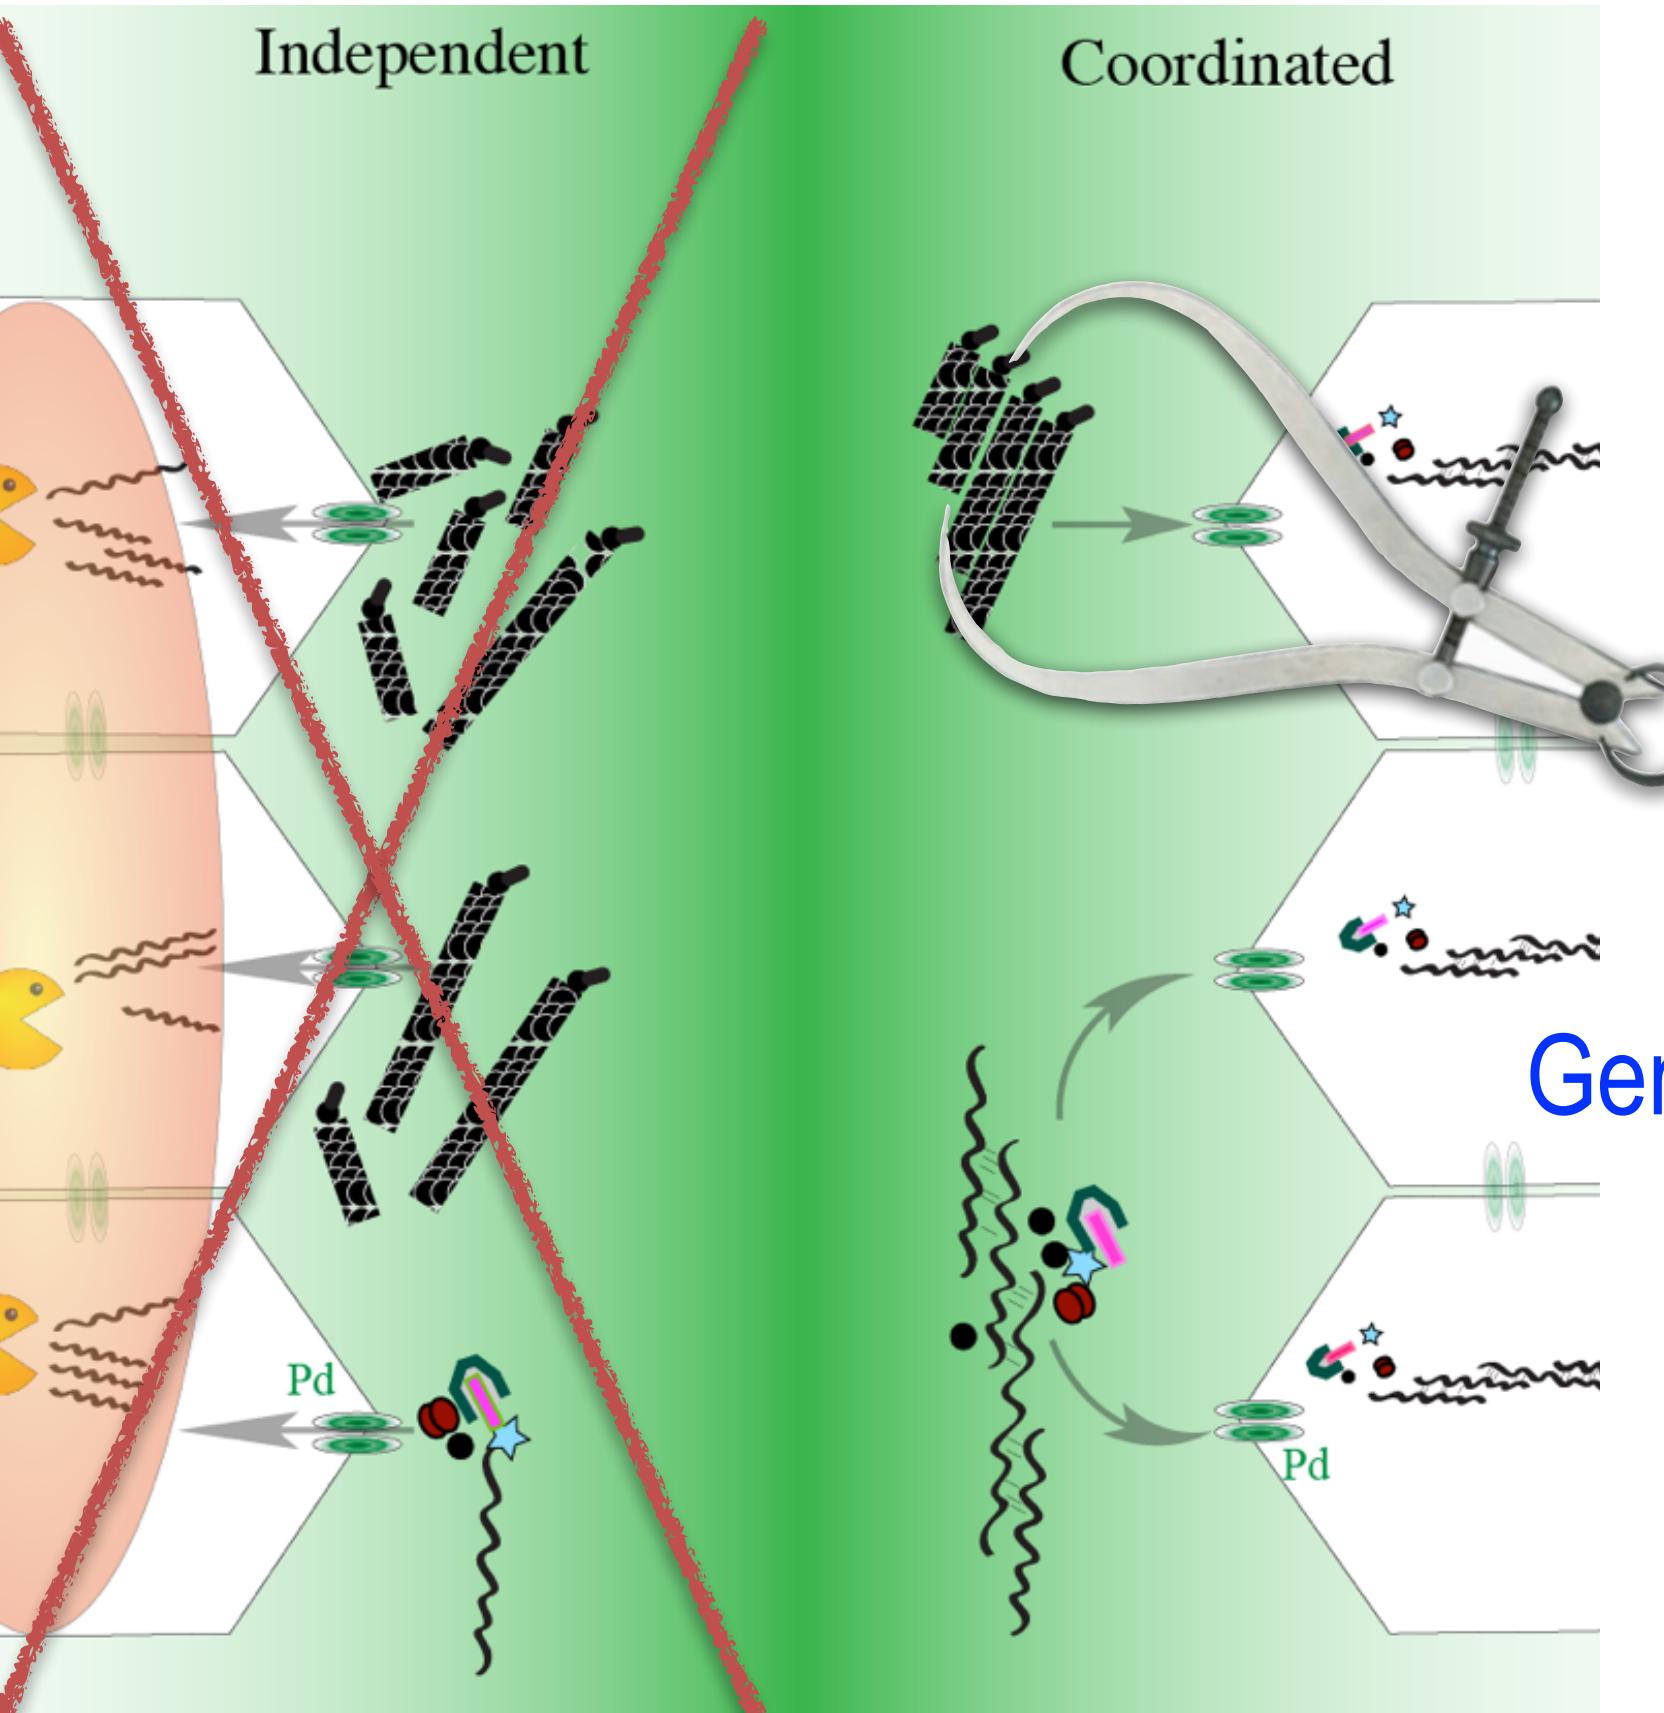

What is moving in plant vascular tissues, how and what consequences ?

Segments are mainly present altogether in single cells

BNYVV long distance movement: A Coordination that requires selection

Virion selection will require molecular Callipers to compile at least one of each size

BNYVV CP is required for long distance movement
BUT encapsidation is not mandatory

Genomic RNA selection will require specific RNA interactions to create an RNA network

Long stretches of perfect base pairing can trigger RNA silencing

→ *Finding the needle in a haystack*

How to find needles in a haystack without a magnet ?

C. quinoa

Local infection

S. oleracea

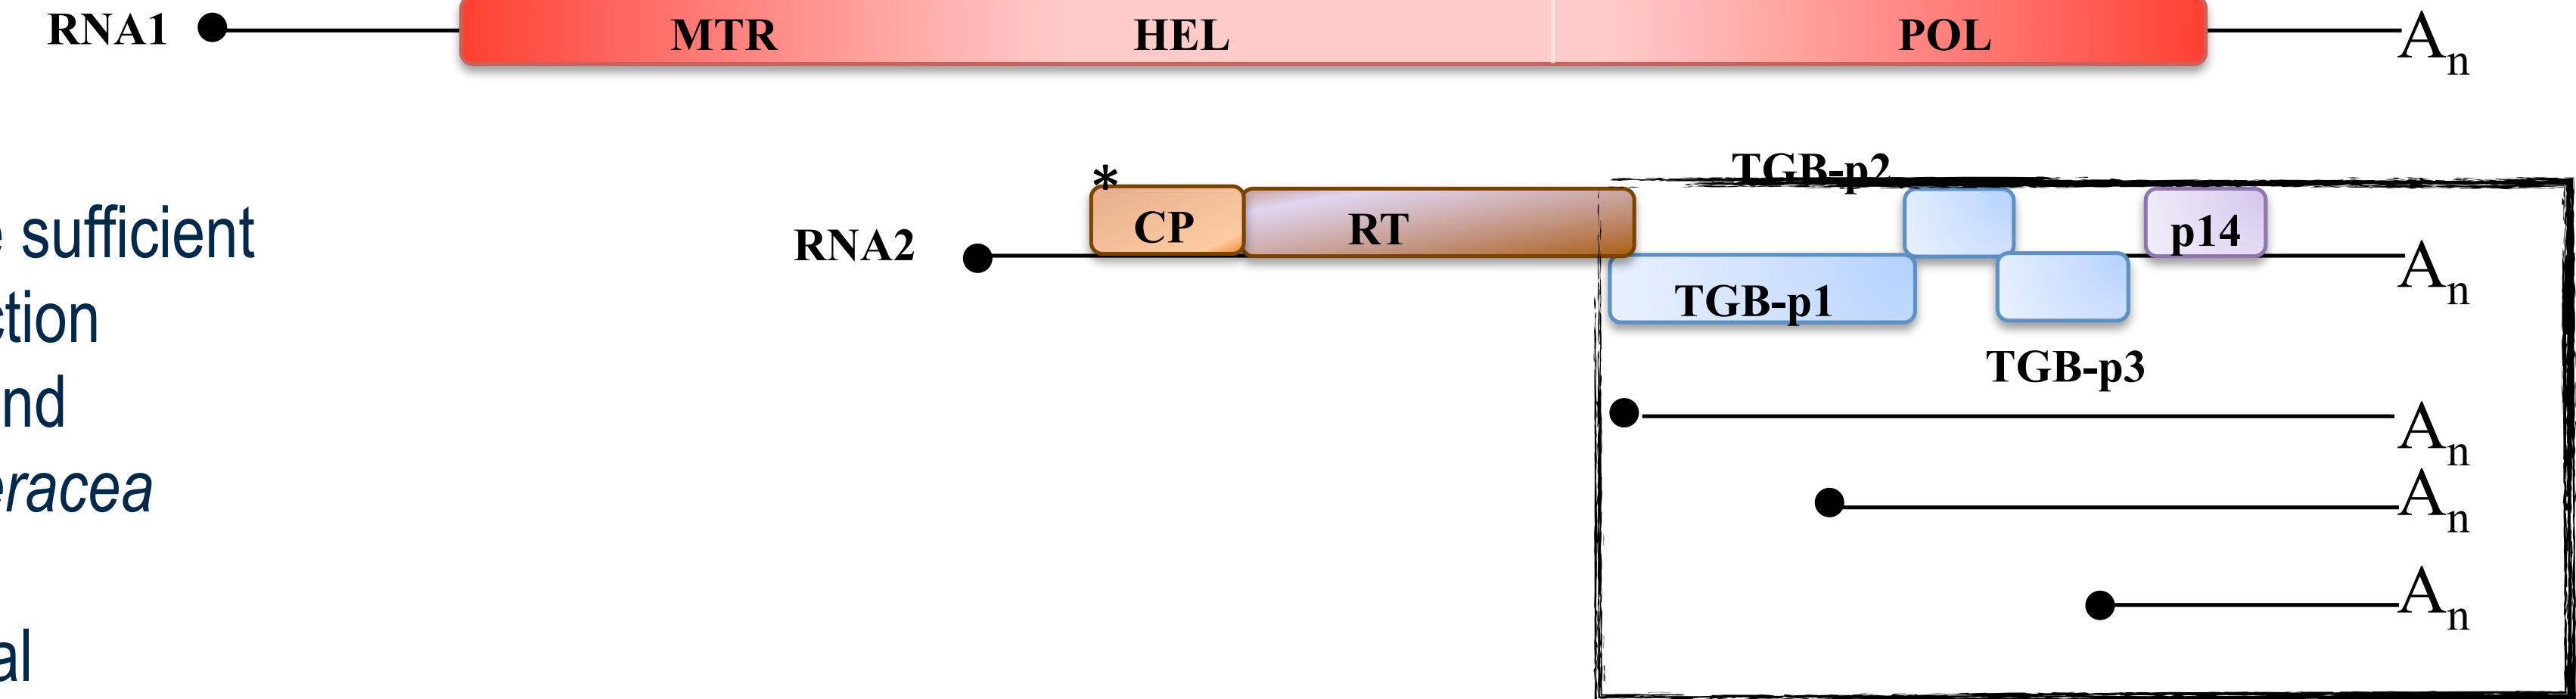

Systemic infection

RNA1 and RNA2 are sufficient
for a productive infection
locally in *C. quinoa* and
systemically in *S. oleracea*

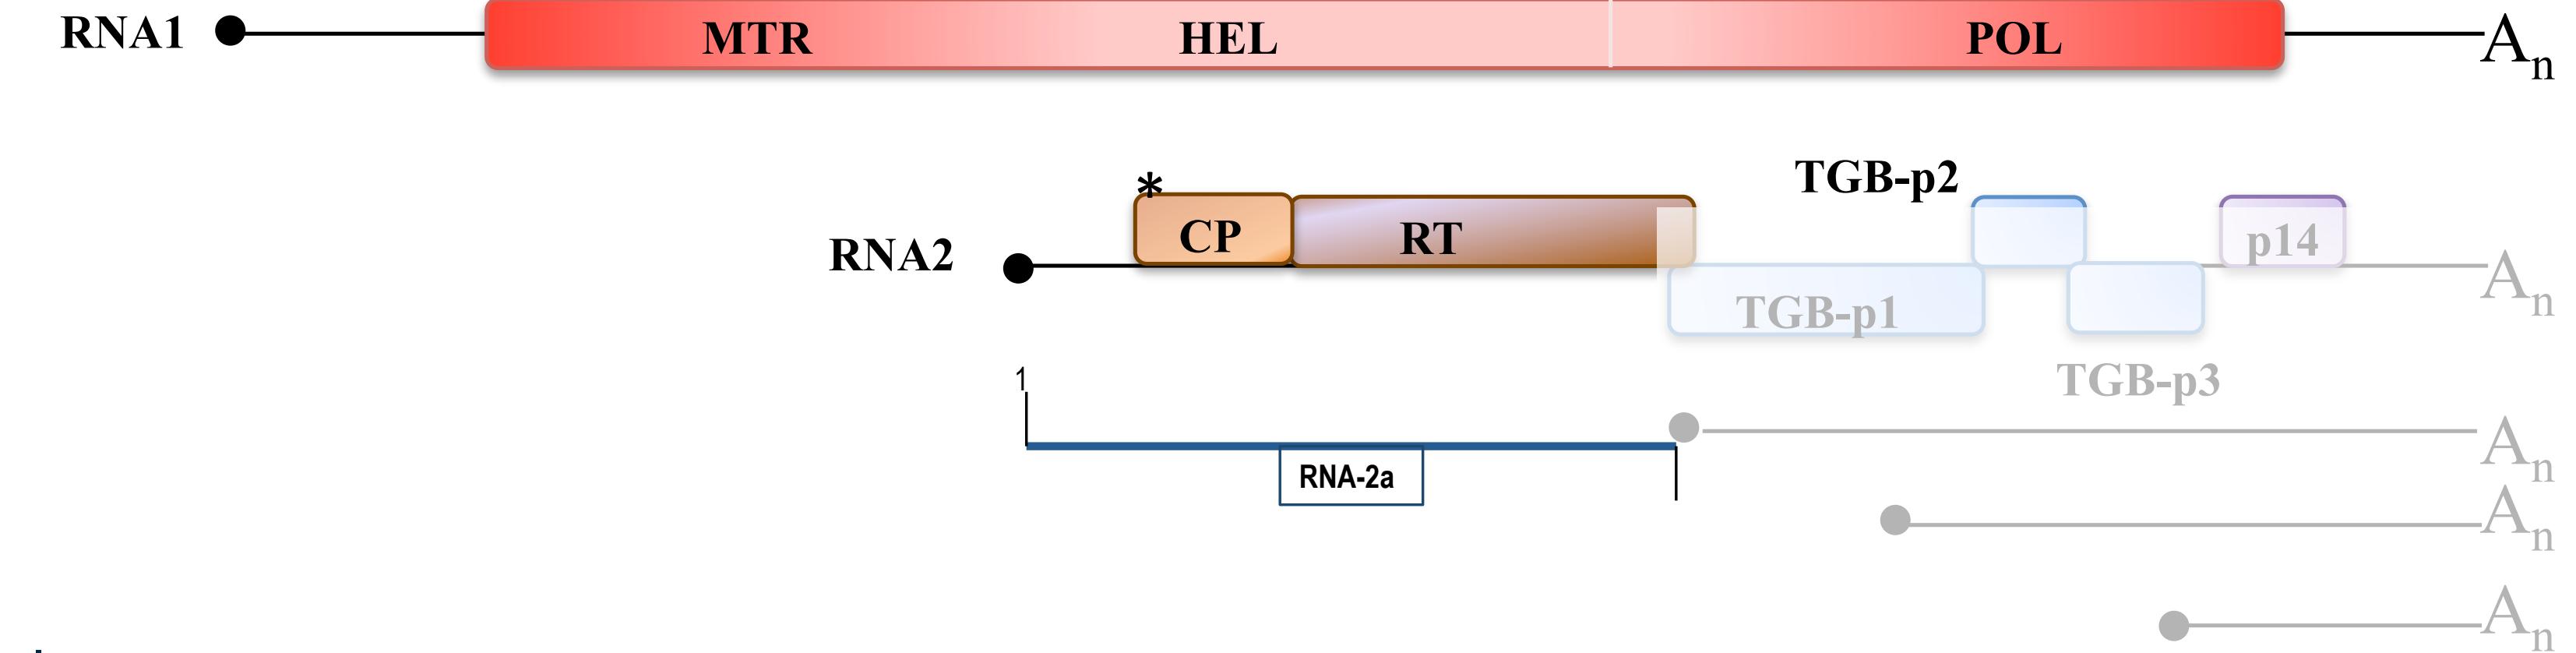

We suspect a minimal
interaction network with RNA1
and RNA2

The interaction(s) domain(s) should be present within the 5' region of RNA2

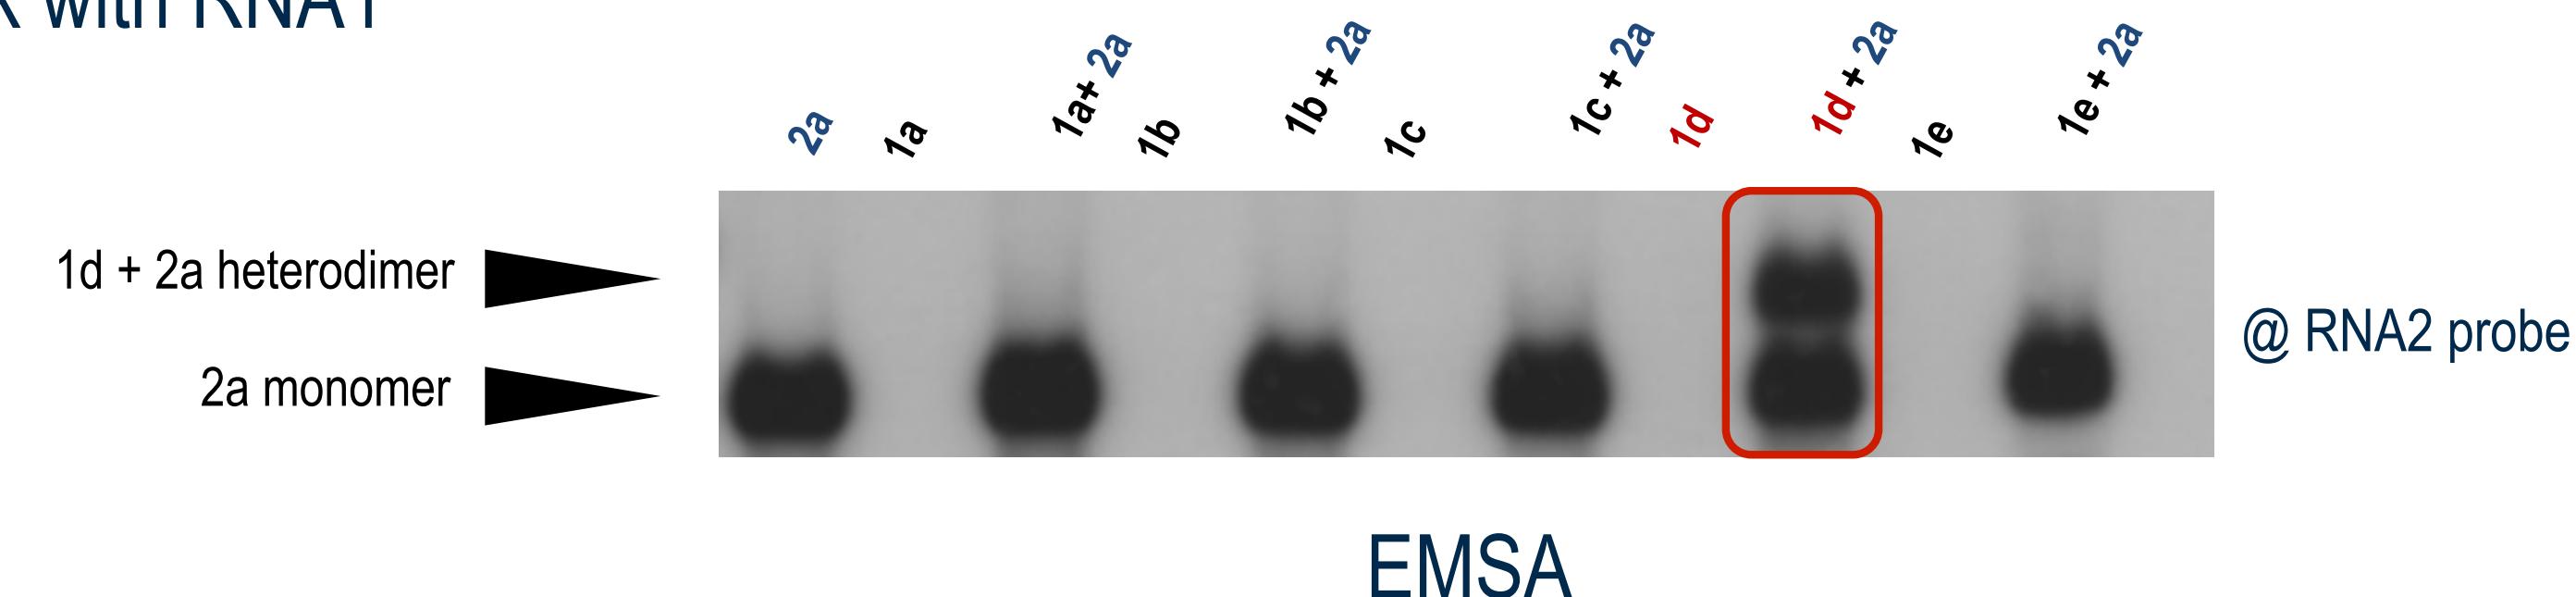

Subgenomic RNAs possess the same 3' sequence :
possible interference with the network

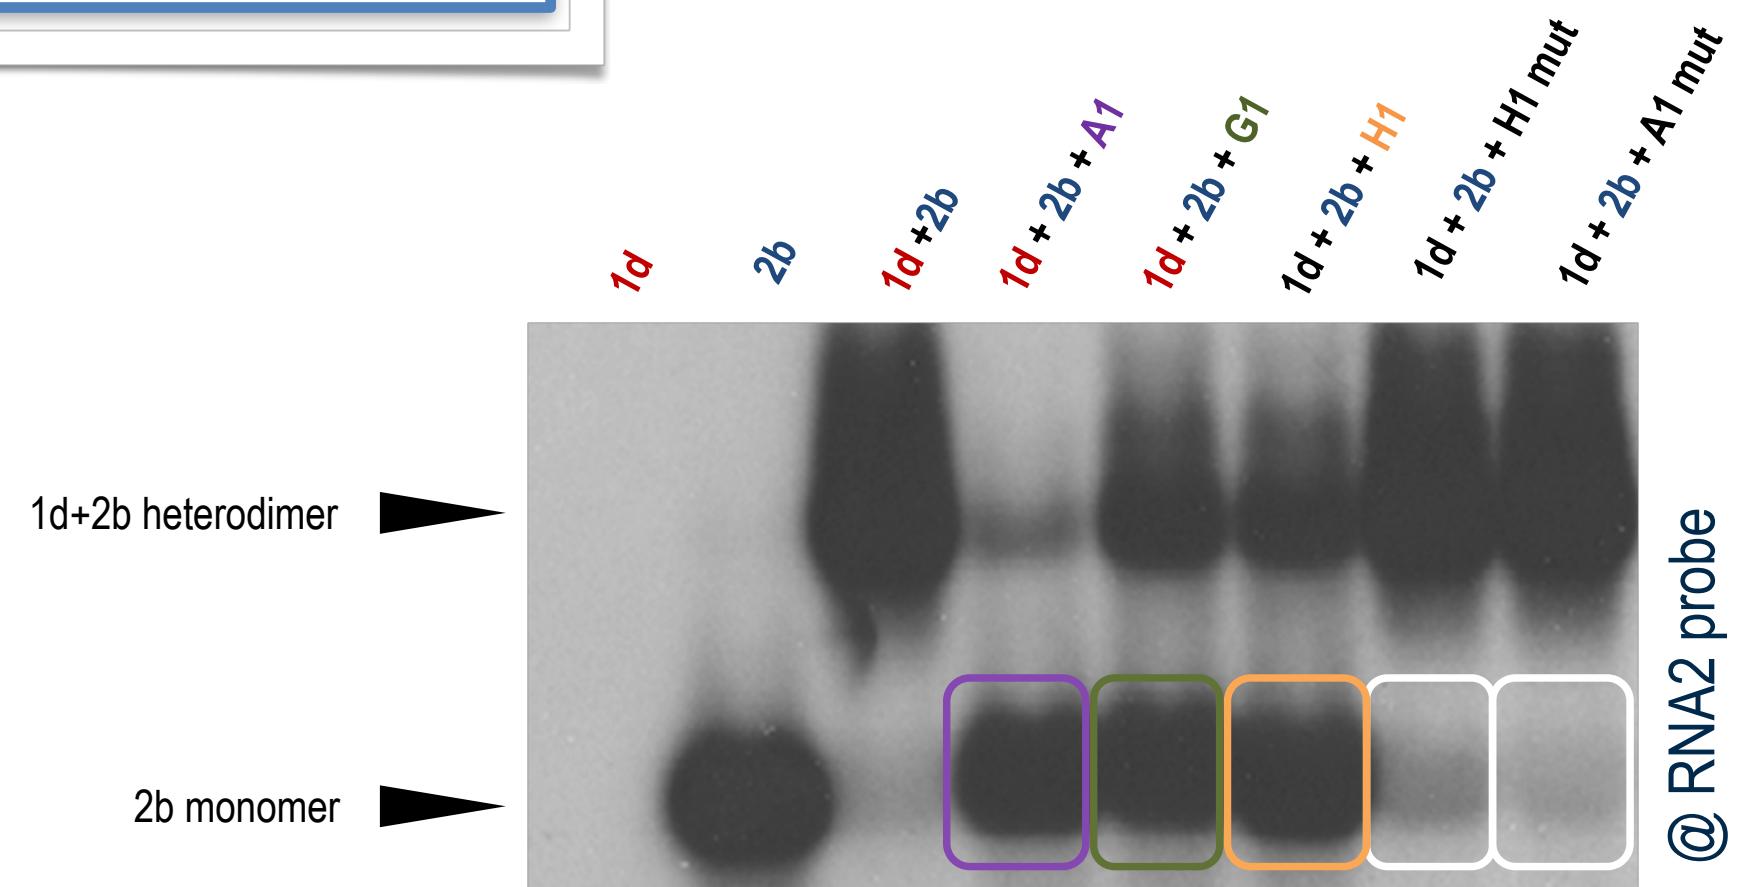

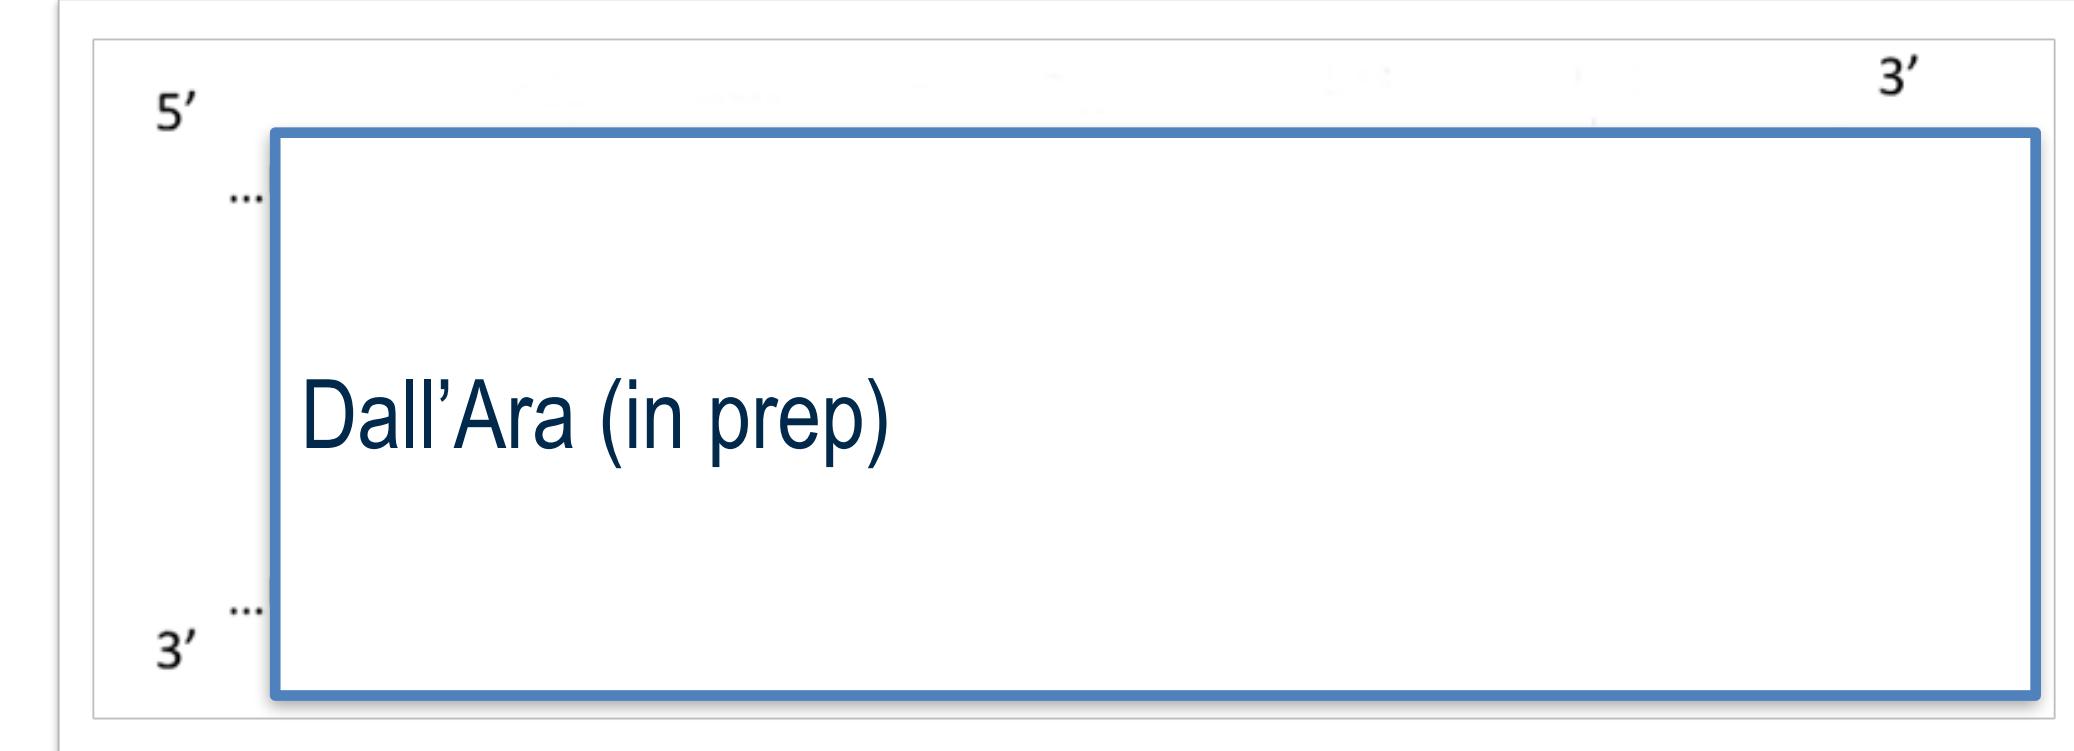

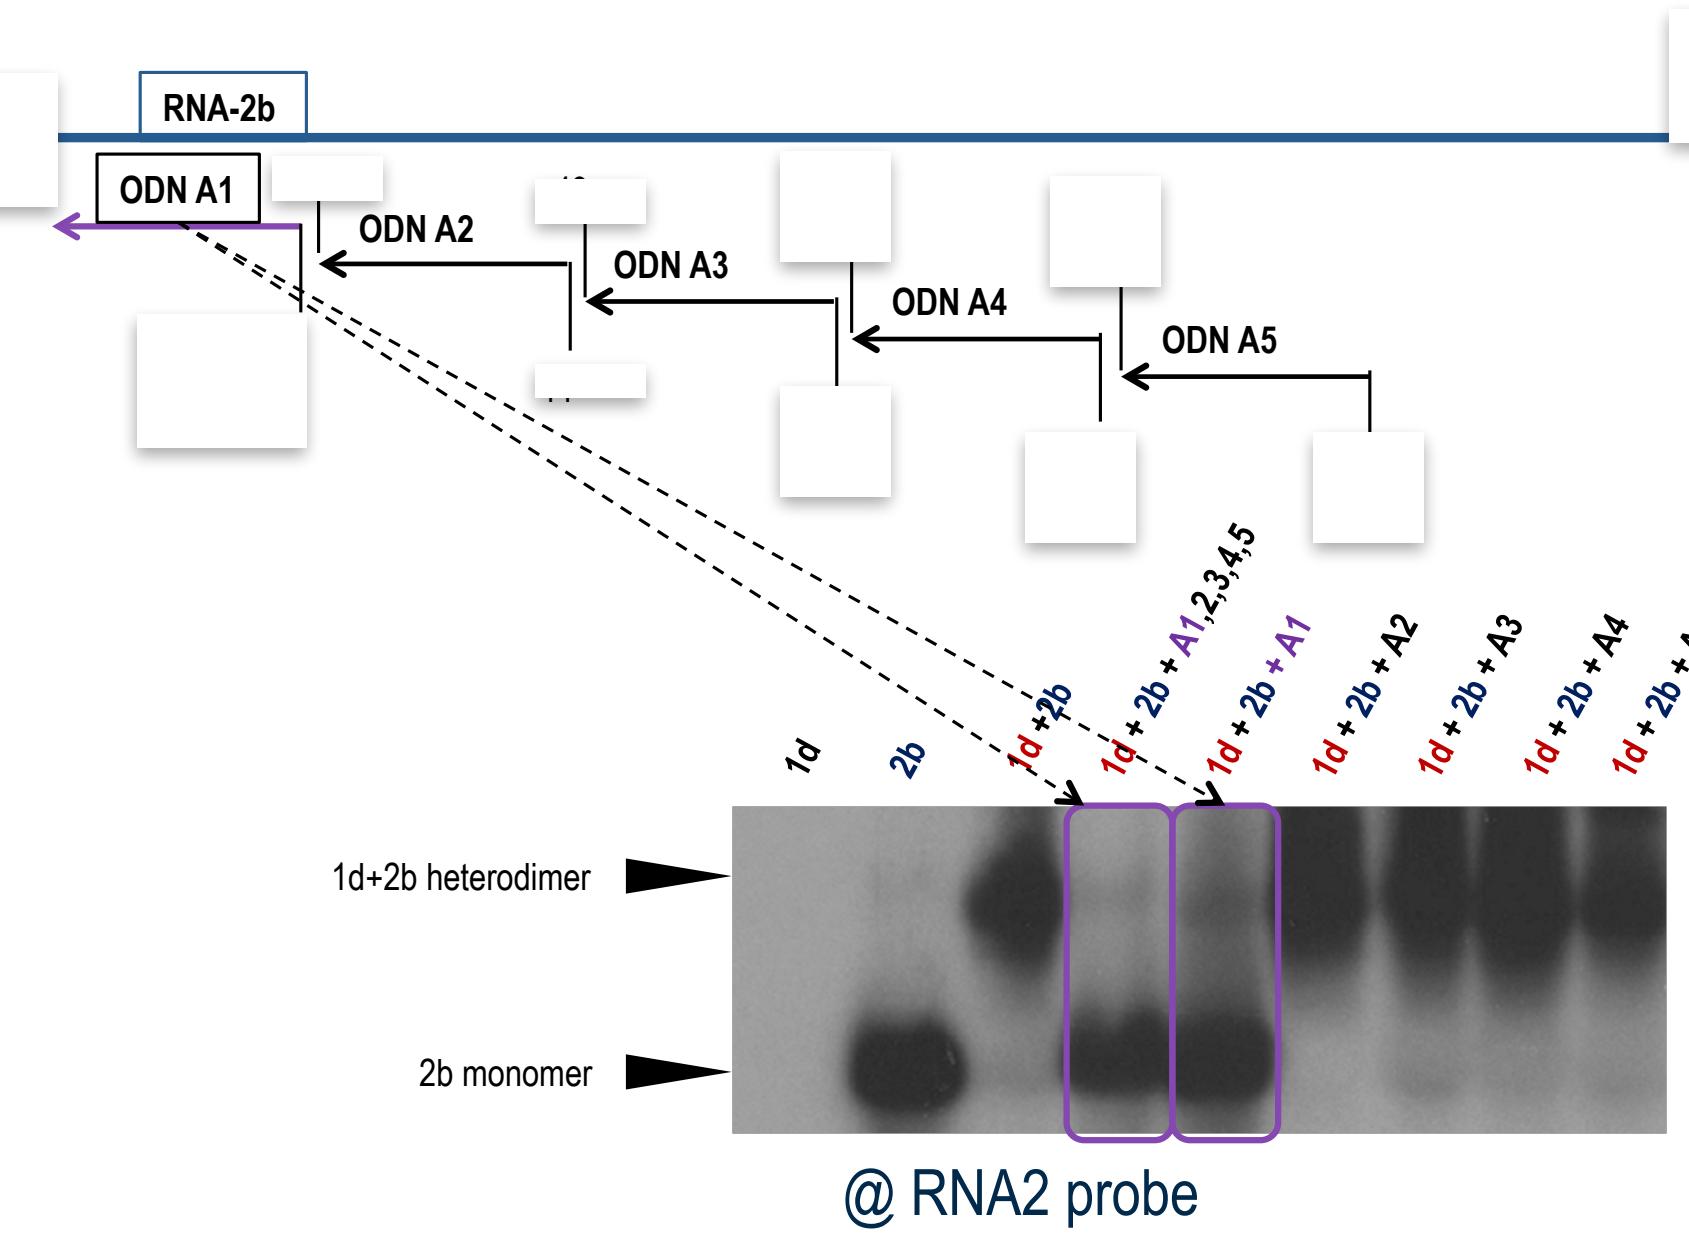

How to find needles in a haystack without a magnet ?

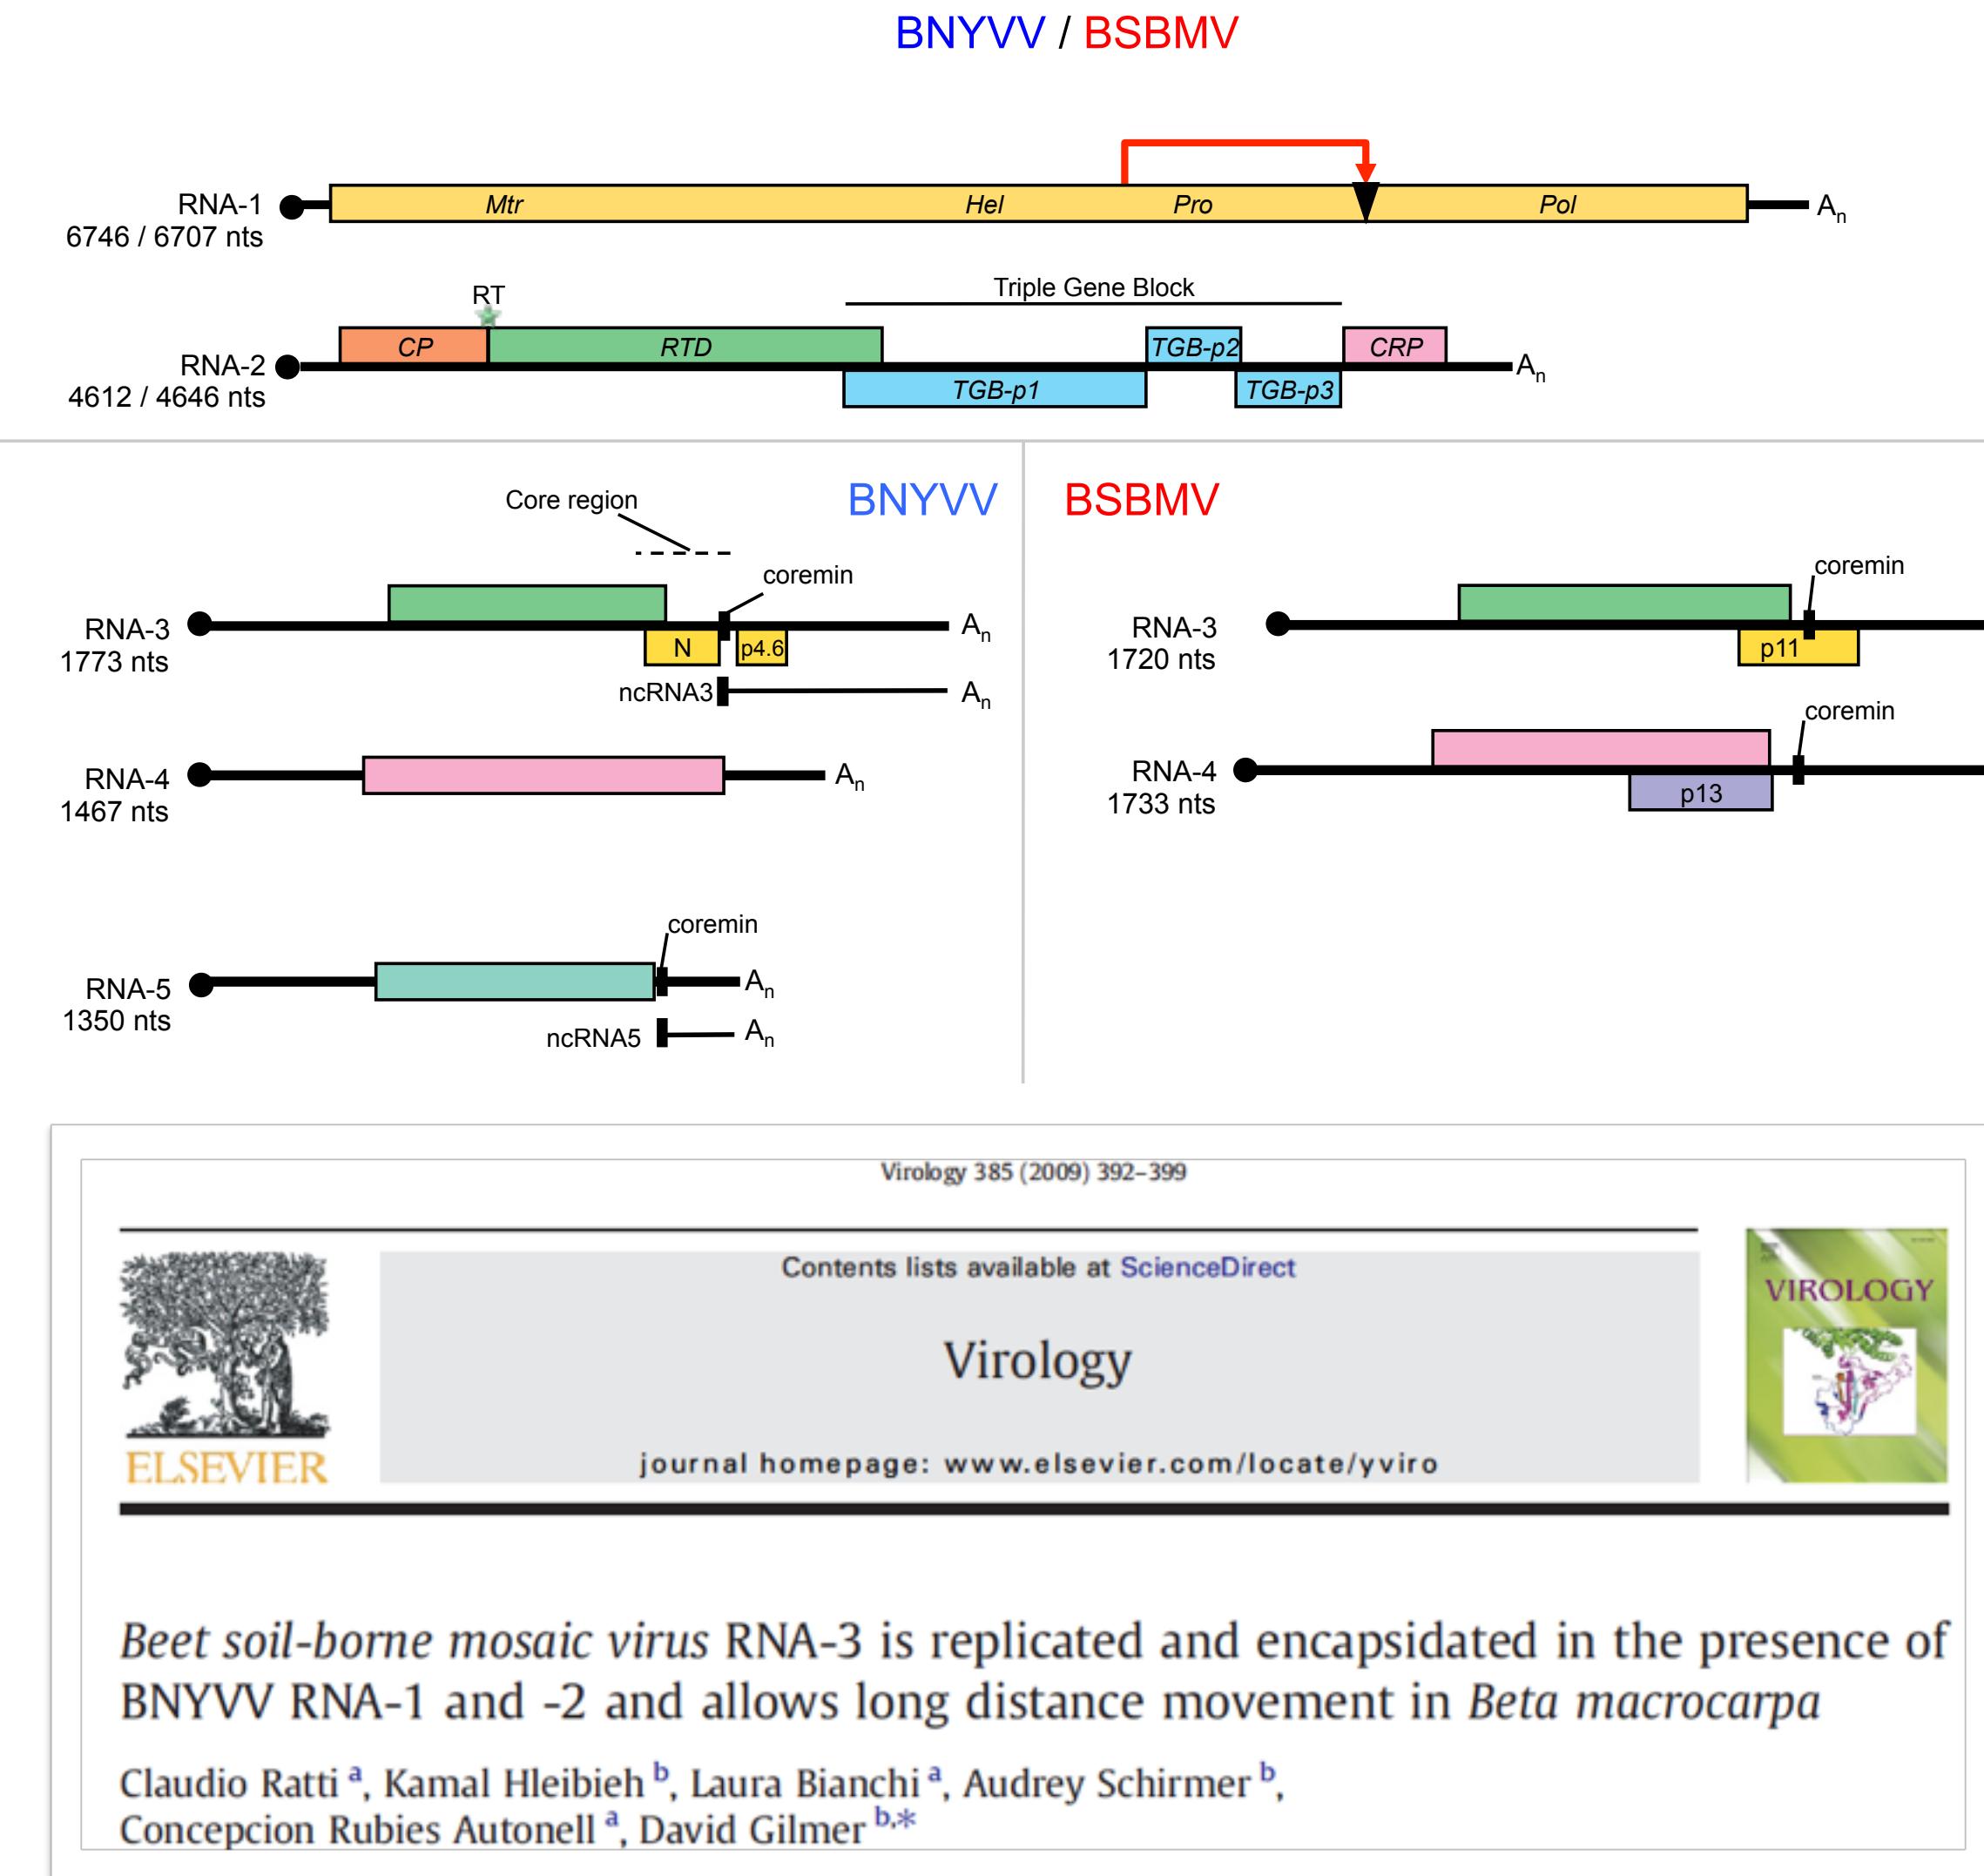

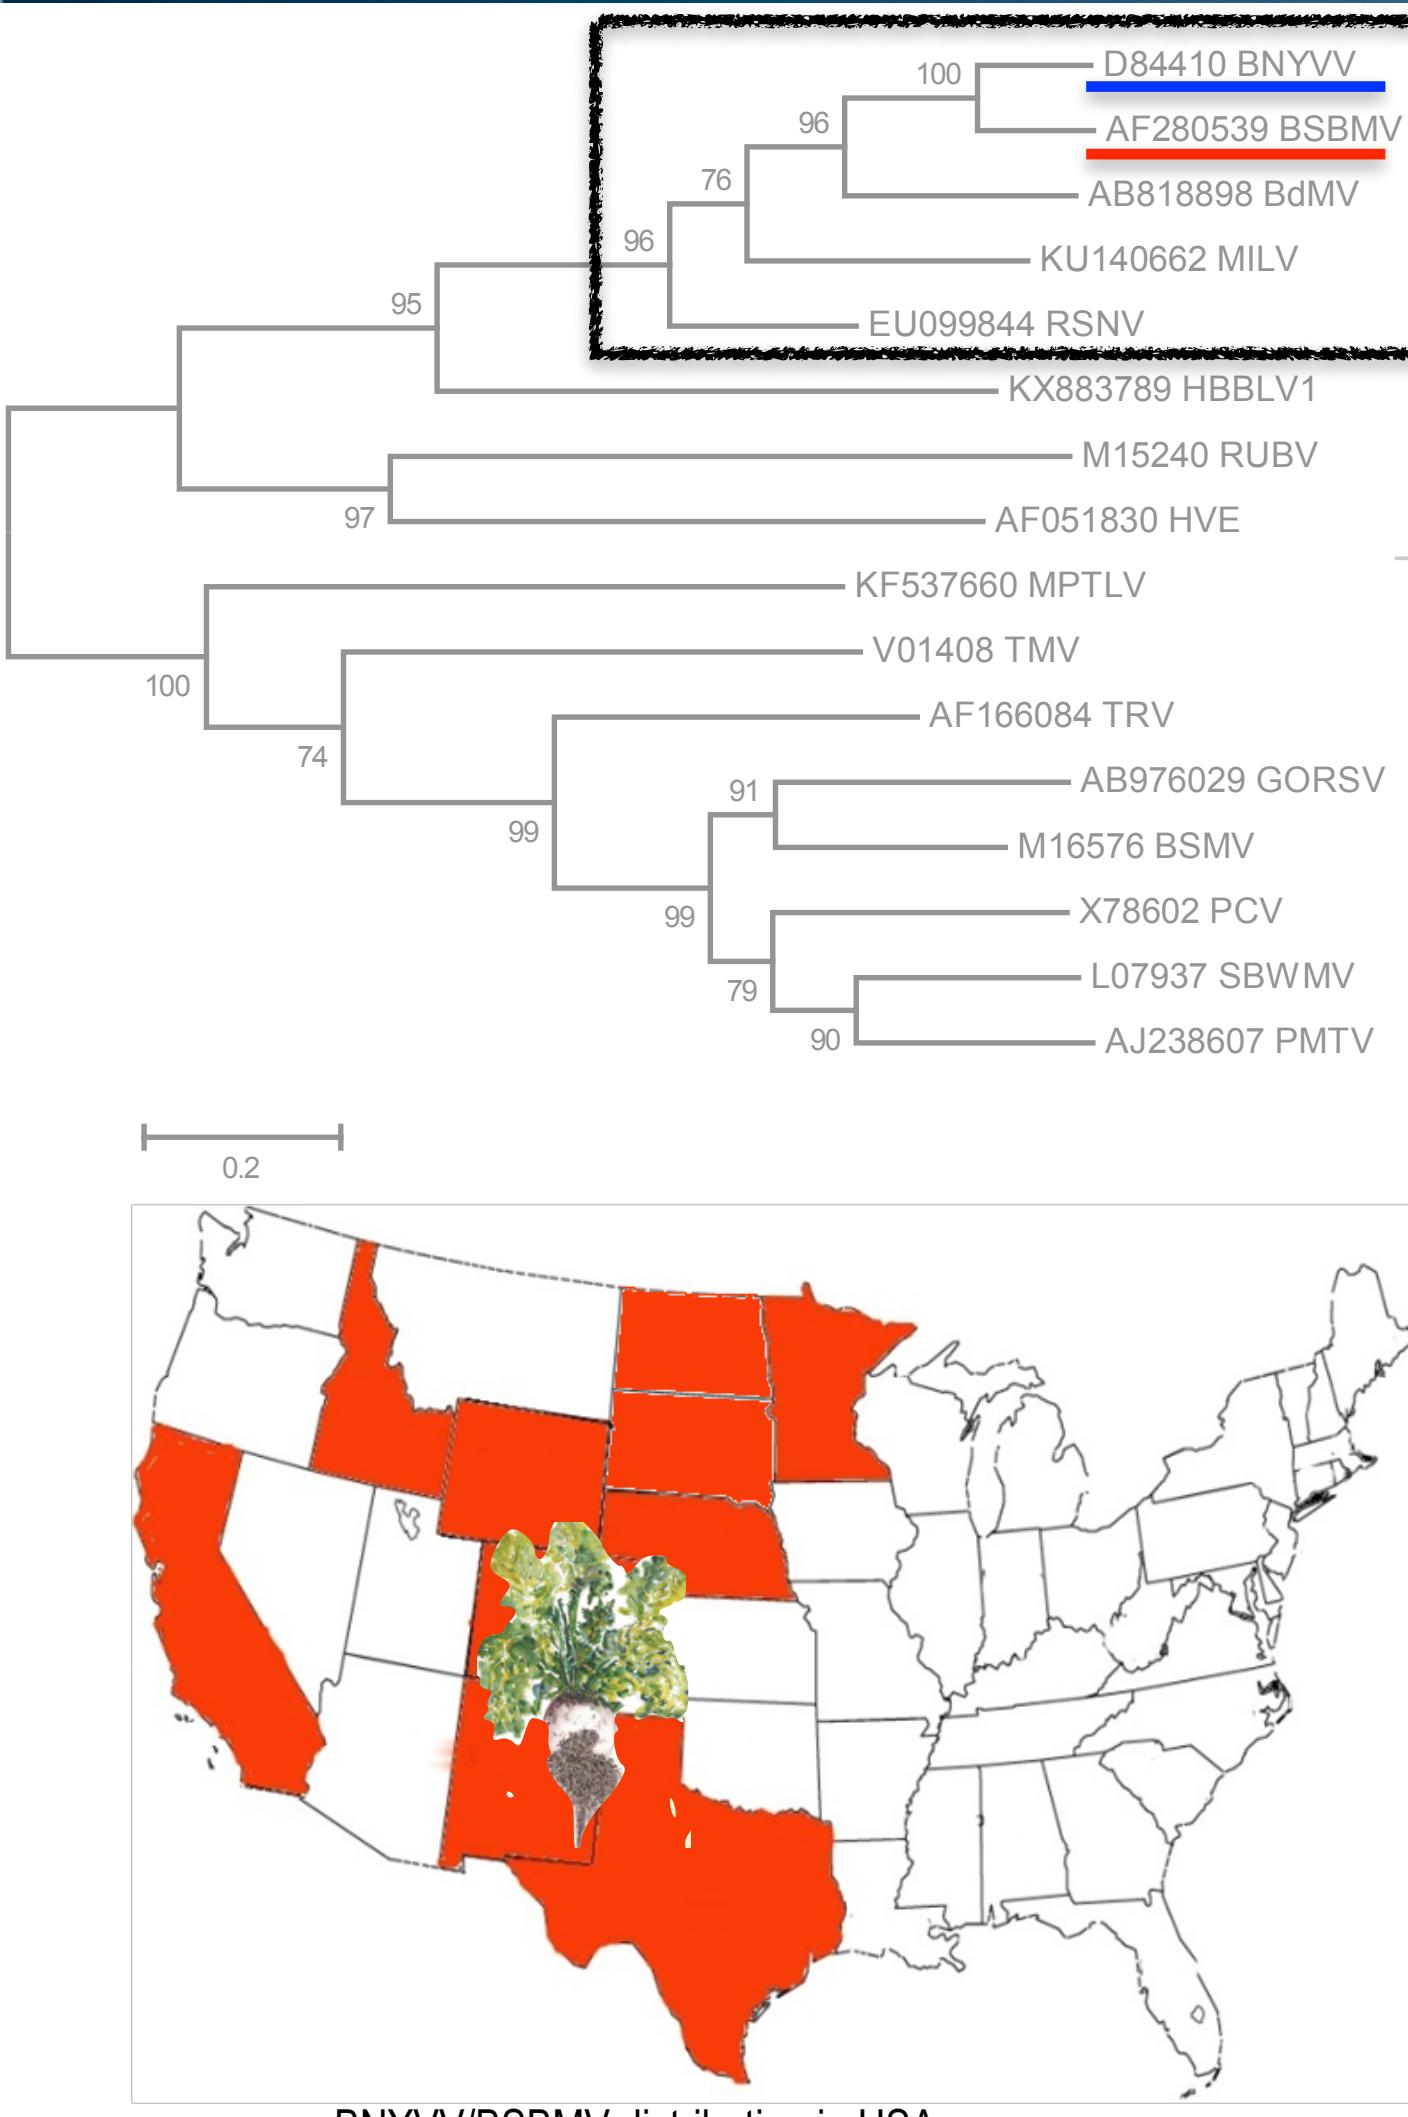

We suspect a minimal interaction network with RNA and RNA2

How to find needles in a haystack without a magnet ?

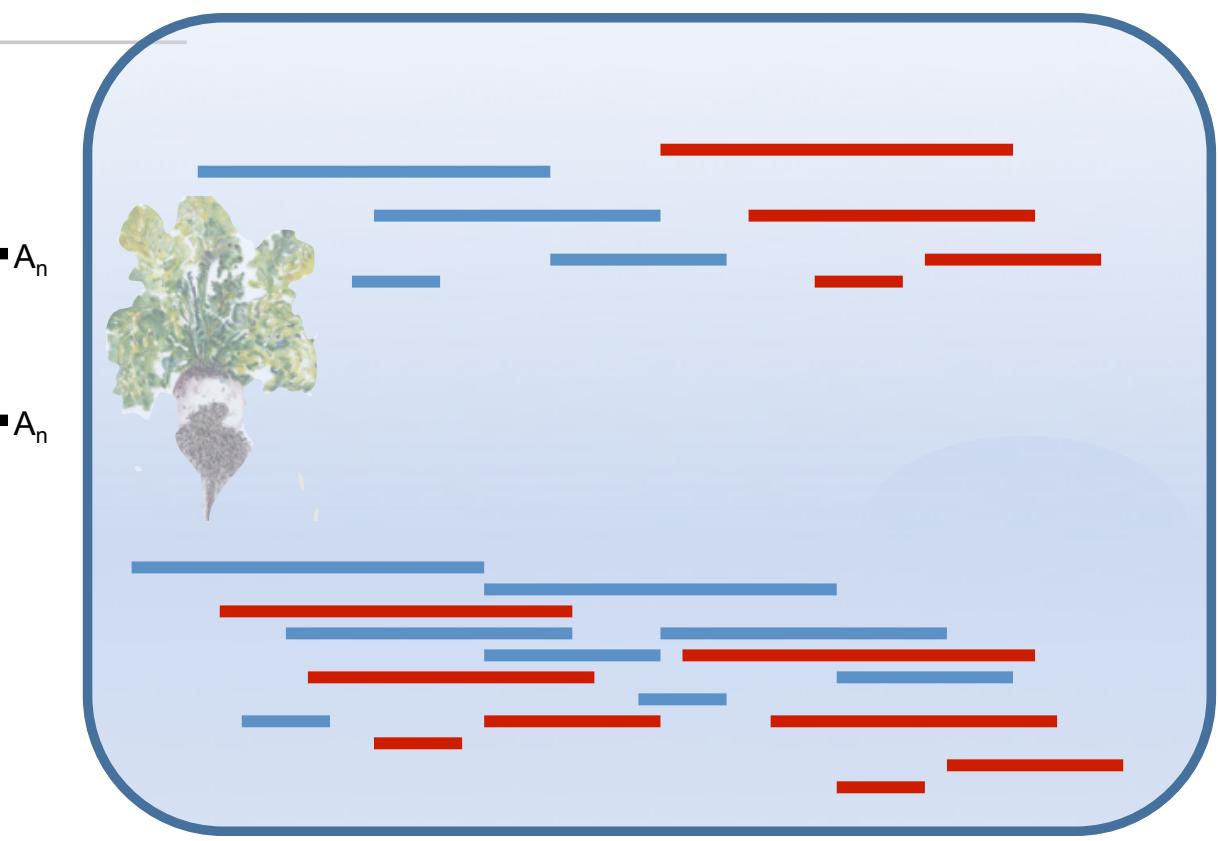

Use of phylogeny

Beet soil-borne mosaic virus RNA-3 is replicated and encapsidated in the presence of BNYVV RNA-1 and -2 and allows long distance movement in Beta macrocarpa
